Anders Møller
Aarhus University

Lugano, ISSTA 2013

The Goal

- Automated testing of event-driven applications
 - Mobile applications
 - Web applications
 - Desktop/GUI applications
- Generation of event sequences
 - High code coverage

The Problem

Example Event Sequence

1. Click button *foo*
2. Click button *bar*
- 3. Input value “1” into field *foobar***
4. Press the back button
5. Click button *baz*
6. Click button “+”
7. Click button “+”

The Problem (cont.)

- Some branches require:
 - Long event sequences
 - Specific event parameters
- Promising methods:
 - *Random, feedback-directed, GUI-driven and fuzz-testing*

The Search Space

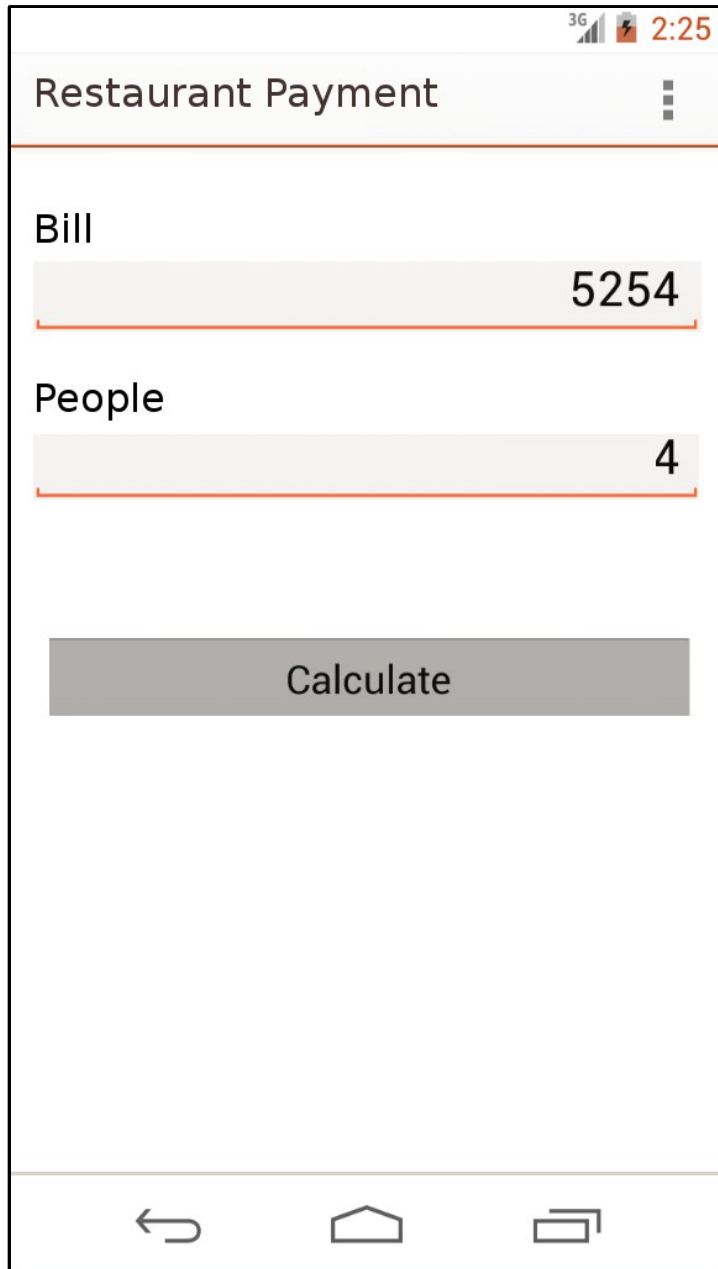

**A targeted method for
event sequence generation for
event-driven applications**

Outline

1. Motivating Example
2. Observations
3. Key Idea
4. Solution and Algorithm
5. Implementation
6. Evaluation
7. Conclusion

Motivating Example

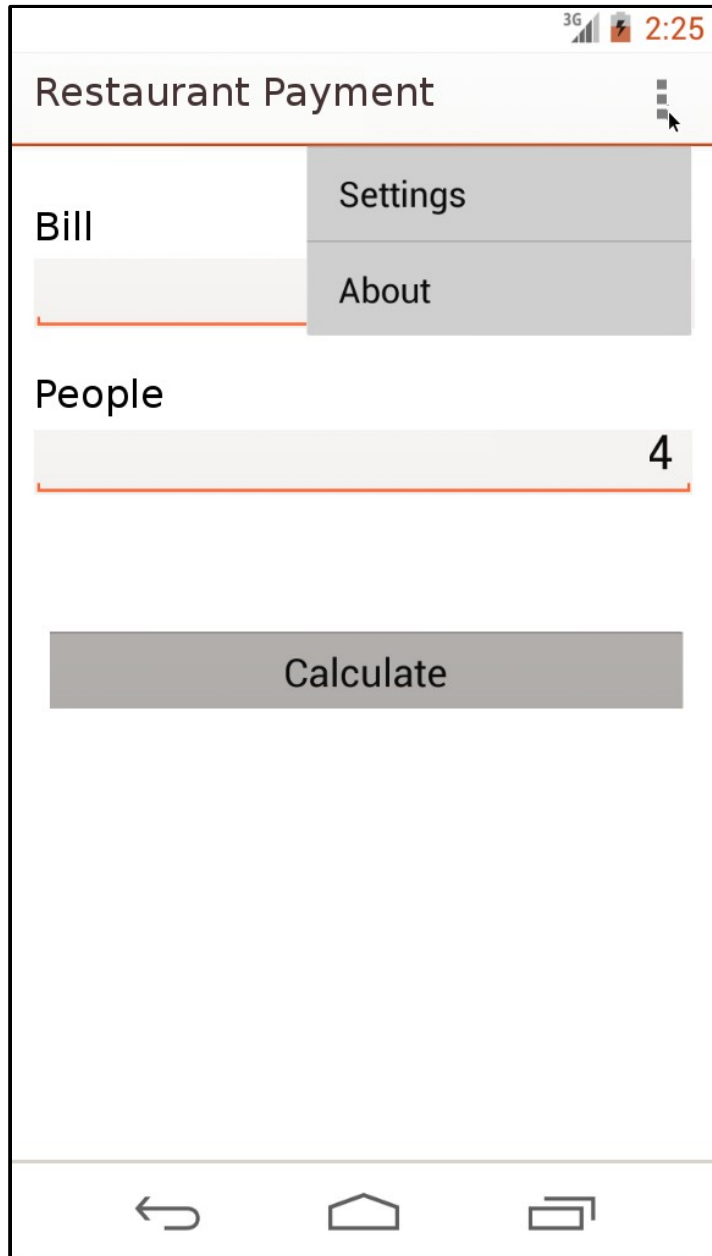

The screenshot shows a mobile application interface titled "Restaurant Payment". At the top, there is a status bar with "3G" signal strength, a battery icon, and the time "2:25". Below the title bar, there is a section labeled "Bill" with a text input field containing the value "5254". Below that, there is a section labeled "People" with a text input field containing the value "4". At the bottom of the form, there is a grey button labeled "Calculate". The bottom of the screen shows the standard Android navigation bar with back, home, and recent apps icons.

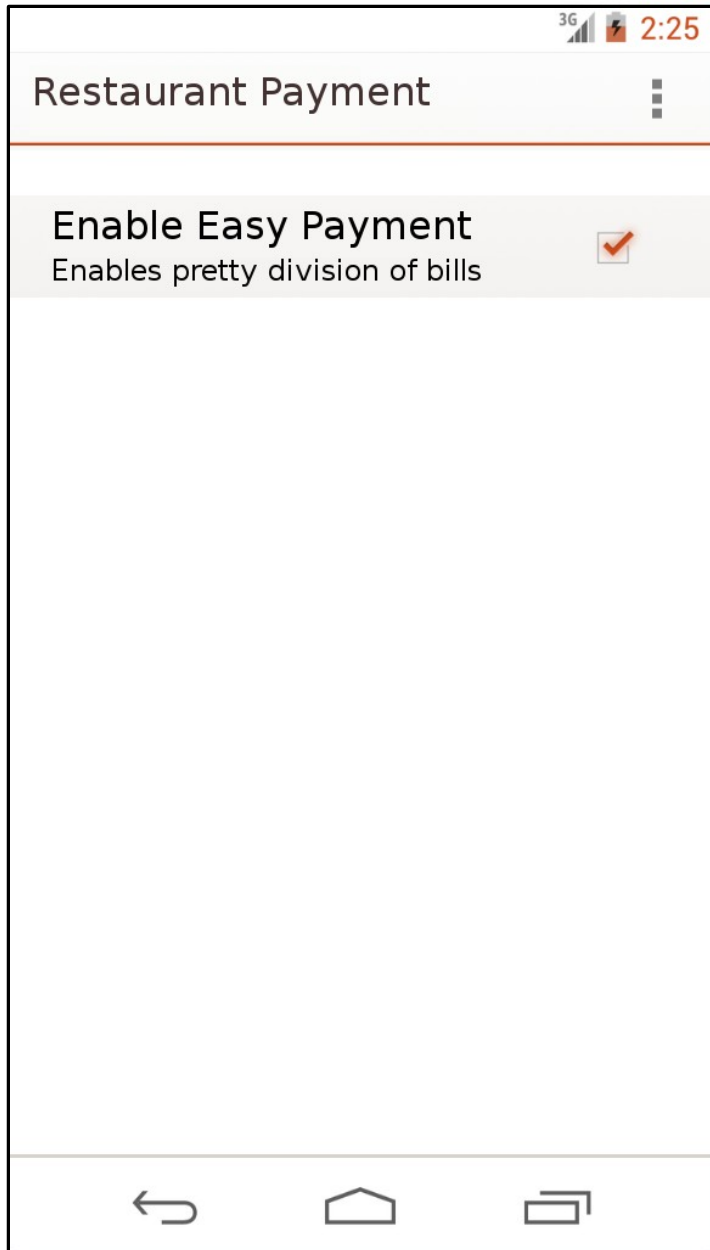

Restaurant Payment
Divide restaurant payments
between participants.

(Simplified version of one of
our benchmarks)

Motivating Example

Motivating Example

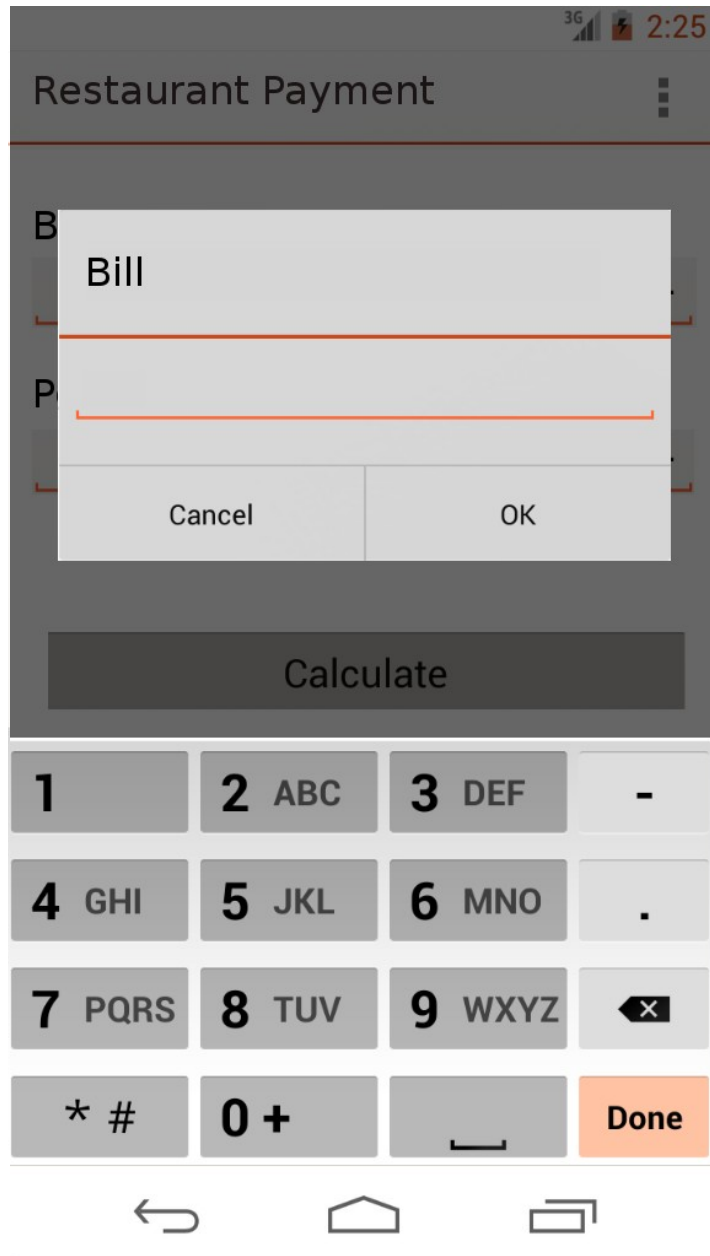

Motivating Example

The image shows a mobile application interface for calculating restaurant payments. At the top, the status bar displays '3G', a battery icon, and the time '2:25'. The app title 'Restaurant Payment' is in the top header, followed by a vertical ellipsis menu icon. Below the header, there are two input fields. The first is labeled 'Bill' and contains the value '5254'. The second is labeled 'People' and contains the value '4'. Both input fields have a light gray background and a thin orange border. Below these fields is a large, gray button labeled 'Calculate'. At the bottom of the screen, there is a white bar with three navigation icons: a back arrow, a home icon, and a recent apps icon.

Field	Value
Bill	5254
People	4

Motivating Example

The app title 'Restaurant Payment' is in the top header, followed by a vertical ellipsis menu icon. Below the header, there are two input fields. The first is labeled 'Bill' and contains the value '5254'. The second is labeled 'People' and contains the value '4'. Both input fields have a light gray background and a thin orange border. Below these fields is a large, gray button labeled 'Calculate'. At the bottom of the screen, there is a standard Android navigation bar with three icons: a back arrow, a home house icon, and a recent apps icon.

Field	Value
Bill	5254
People	4

Motivating Example

The actual calculation

```
int bill = this.appState.enteredAmount;
int people = this.appState.numberOfPeople;
boolean useEasyPay = this.appState.numberOfPeople;

if (useEasyPay) {
    ...

    if (bill < people) {
        ... // interesting calculations
        return
    }

    ...
}
```

Motivating Example

The actual calculation

```
int bill = this.appState.enteredAmount;  
int people = this.appState.numberOfPeople;  
boolean useEasyPay = this.appState.numberOfPeople;
```

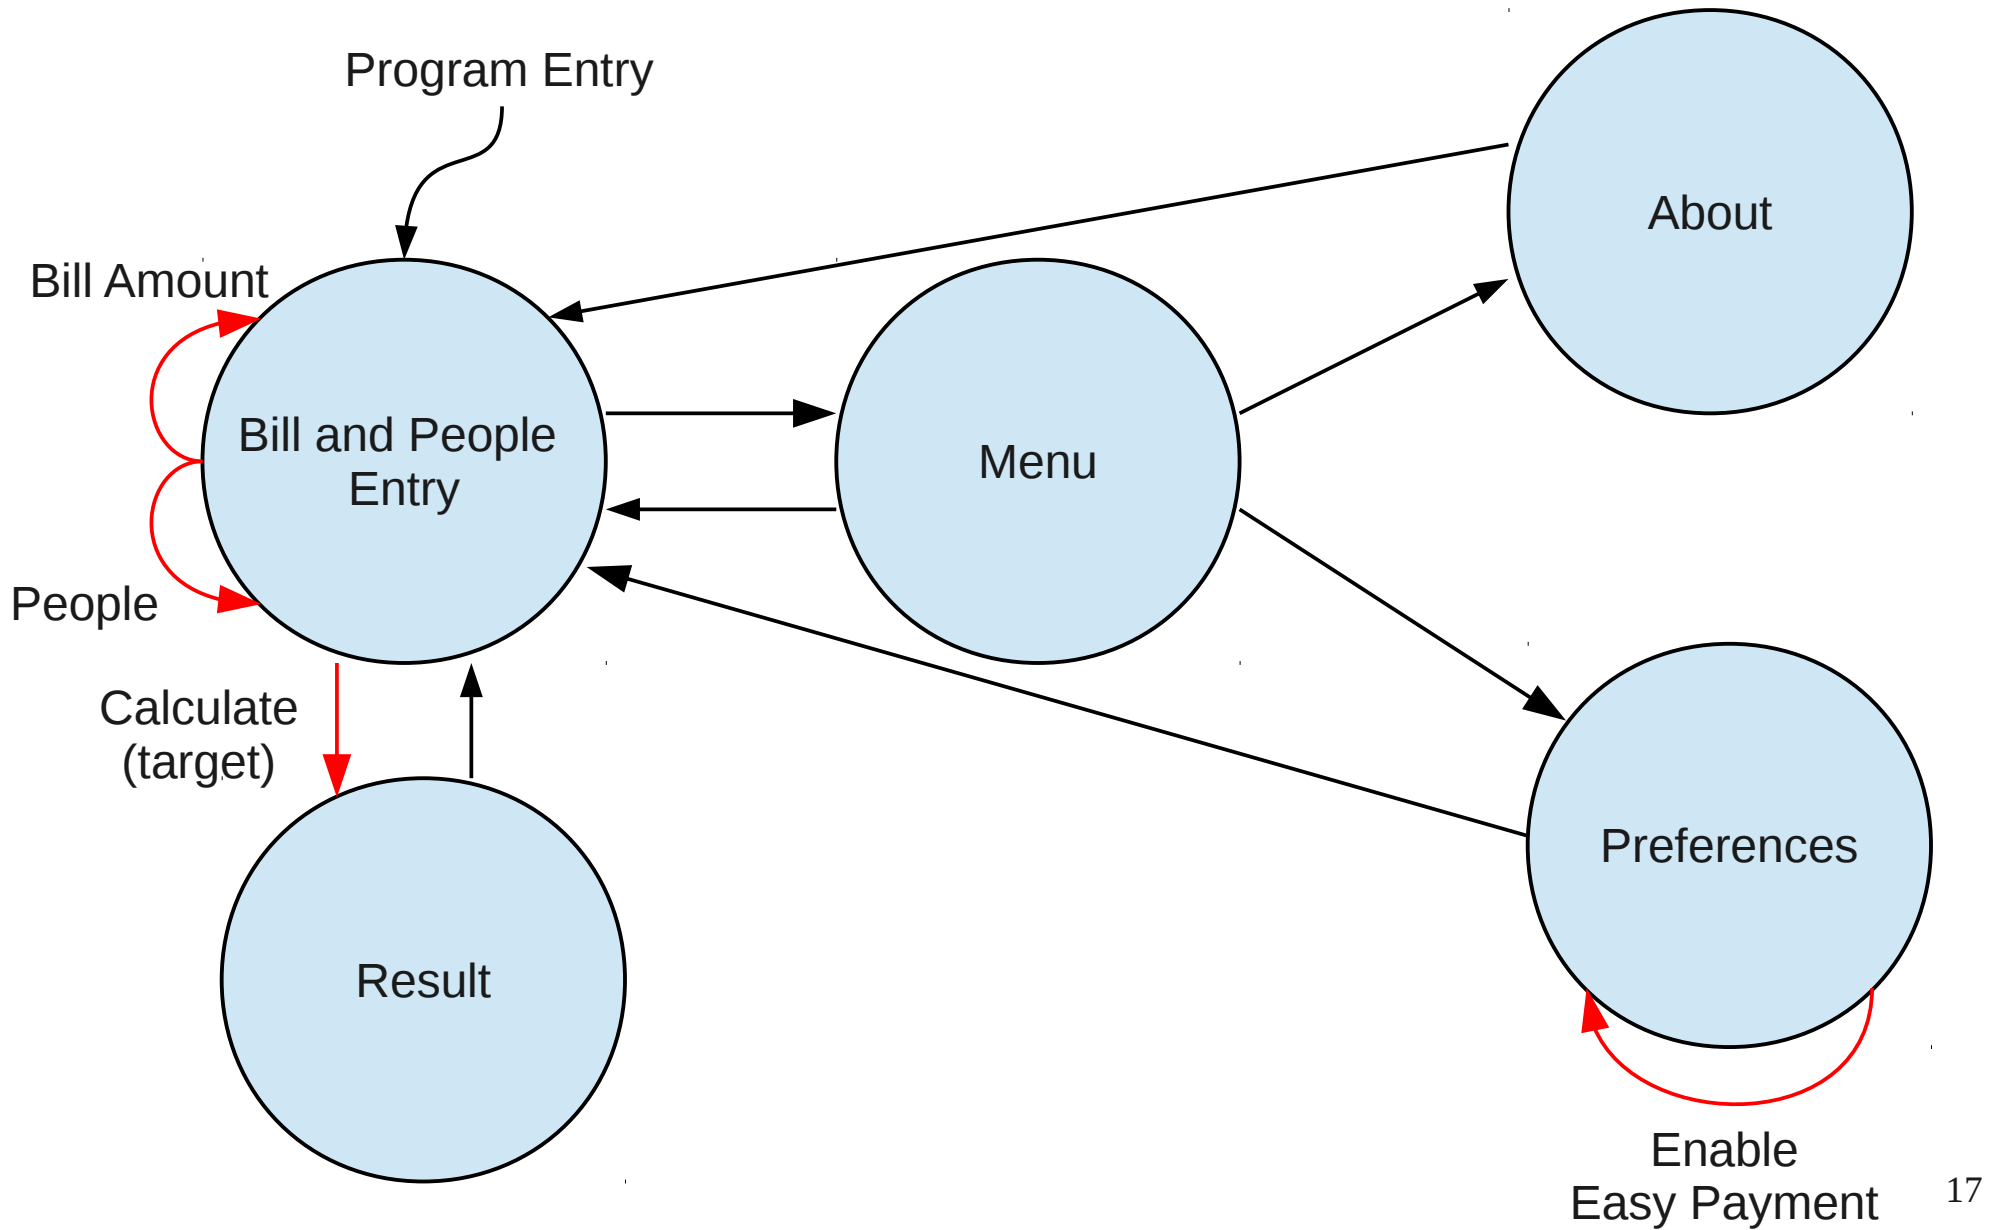

```
if (useEasyPay) {  
    ...  
  
    if (bill < people) {  
        ... // interesting calculations  
        return  
    }  
  
    ...  
}
```

```
useEasyPay ^ bill < people
```

Observation 1

- A branch (target) **depends** on program state
- Some events (“anchor events”) **mutate** relevant program state
- The relevant program state is mutated at a limited number of program points
 - Only focusing on these points reduces the search space

UI Model

Observation 2

- **Anchor events** connected by **connector events**
- Program state is unaffected by connector events
 - The program state dependent on by the target
- Any feasible path between anchors will do

Key Idea

- For a **target branch**:
 - identify a sequence of **anchors**
 - changing **program state**
 - satisfying the target branch's dependencies
- Focus on *anchors*, omitting unrelated parts of the application
- **Discard** infeasible sequences as early as possible

The Search Space

The Search Space

The Search Space

Our Solution

Targeted Sequence Generation
using
UI Models and Concolic Testing

Recall: Concolic Testing

- Symbolic and Concrete execution
- Explore the execution space of a program
 - Uses a constraint solver

```
1 void func(int a, int b) {  
2     if (a == 5) {  
3         if (b != 5) {  
4             return 0; ← a = 5 ∧ b ≠ 5  
5         }  
6         return 1; ← a = 5 ∧ b = 5  
7     }  
8     return 2; ← a ≠ 5  
9 }
```

Our High-level Algorithm

(1) Summarization Phase

Run concolic testing on each event handler

- Path conditions for individual program traces
- Dependencies / program mutation

(2) Sequence Generation Phase (repeat for each target)

Backward search, starting with a *target branch* and backward to an entry point

- Uses UI models, path conditions, dependencies

Implementation

Collider

Automated testing of Android mobile applications

- Implemented using:
 - Symbolic-JPF (solver infrastructure)
 - The Android Emulator (concrete execution)
- Targets the Dalvik bytecode level
 - only a compiled executable is required for testing

Evaluation

- Study on 5 Android applications
- Random testing (Monkey) and UI-driven testing is used to reach a number of targets
- Of 99 unreached targets:
 - **Collider reaches 46 of these**
 - Remaining unreached mainly due to limitations in the constraint solver
 - Phase 1: 3 to 5 hours
Phase 2: 2 seconds to 30 minutes

Conclusion

- A new method for targeted *event sequence* generation
- Search is guided through *concolic testing* and *UI-models*
- Implementation and evaluation shows the potential of the method
- Generation of sequences of events for reaching highly constrained targets
