# On the Performance of Private Set Intersection 

Benny Pinkas, Bar-Ilan University
Thomas Schneider, TU Darmstadt Michael Zohner, TU Darmstadt

## Private Set Intersection (PSI)

Input:
Output:
$X=x_{1} \ldots x_{n}$
$X \cap Y$ only
$Y=y_{1} \ldots y_{n}$
Server
nothing

Other variants exist (e.g., both parties learn output; client learns size of intersection; compute some other function of the intersection, etc.)

## Applications

- PSI is a very natural problem
- Matching
- Testing human genomes [BBC+11]
- Proximity testing [NTL+11]
- Relationship path discovery in social networks [MPGP09]
- Intersection of suspect lists
- Botnet detection [NMH+10]
- Cheater detection in online games [BHLB11]

## This talk

- Survey the major results
- Suggest optimizations based on new observations
- Present a new scheme
- Compare the performance of all schemes
- On the same platform
- Using the best optimizations that we have

## A naïve PSI protocol

- A naïve solution:
- Have A and B agree on a "cryptographic hash function" H()
- $B$ sends to $A: H\left(y_{1}\right), \ldots, H\left(y_{n}\right)$
- A compares to $\mathrm{H}\left(\mathrm{x}_{1}\right), \ldots, \mathrm{H}\left(\mathrm{x}_{\mathrm{n}}\right)$ and finds the intersection
- Does not protect B's privacy if inputs do not have considerable entropy

## Preliminaries

- We set the security parameter to 128 bits
- Namely, use symmetric and public key systems against which the best brute force attack takes $2^{128}$ operations.

## Preliminaries

- We only consider semi-honest (passive) adversaries
- In crypto we consider two types of adversaries:
- Semi-honest (aka honest-but-curious) adversaries follow the protocol but try to learn more than they should
- Malicious adversaries can behave arbitrarily
- Why discuss only semi-honest?
- There are PSI protocols secure against malicious adversaries
- These protocols are much less efficient
- None of them was implemented [FNP04, JL09, HN10, CKT10, FHNP13].
- We use OT extension...

## ;) PSI secure against malicious adversaries [FHNP]

| $\underline{P_{1}\left(X, m_{2}\right)}$ |  | $\underline{P_{2}\left(Y=\left\{y_{\alpha}\right\}_{\alpha \in\left\{1 \ldots m_{2}\right\}}, m_{1}\right)}$ |
| :---: | :---: | :---: |
| $\begin{array}{r} 1^{k} \\ \left(p k, s k_{1}\right) \end{array}$ | $\pi_{\text {KEY }}$ | $\begin{aligned} & \longleftarrow 1^{k} \\ & \longrightarrow\left(p k, s k_{2}\right) \end{aligned}$ |
|  | $E_{p k}\left(Q_{1}(\cdot)\right) \ldots E_{p k}\left(Q_{B}(\cdot)\right)$ |  |
| $Q_{1}(\cdot) \ldots Q_{B}(\cdot) \longrightarrow$ | $\pi_{\text {PoLY }}$ | $\begin{aligned} & \longleftrightarrow E_{p k}\left(Q_{1}(\cdot)\right) \ldots E_{p k}\left(Q_{B}(\cdot)\right) \\ & \longrightarrow 0 / 1 \end{aligned}$ |
| Verify $s k=s k_{1}+s k_{2}$ | $s k_{2}$ |  |
|  | $\begin{gathered} e_{j}^{\alpha}=E_{p k}\left(r_{j} \cdot q_{j}+s_{1-j}^{\alpha} ; \hat{r}_{j}\right), \\ t_{\alpha}=\tilde{r}_{j} \oplus y_{\alpha} \end{gathered}$ | $\begin{aligned} & \text { For all } \alpha \in\left\{1 \ldots m_{2}\right\}, j \in\{0,1\}: \\ & \quad s_{0}^{\alpha}, s_{\alpha}^{\alpha} \leftarrow_{R} \mathbb{M}, \\ & \mathcal{H}\left(s_{j}^{\alpha}\right) \rightarrow r_{j}\left\\|\tilde{r}_{j}\right\\| \hat{r}_{j} \\ & q_{j} \stackrel{\text { def }}{=} Q_{h_{j}\left(y_{\alpha}\right)}\left(y_{\alpha}\right) \end{aligned}$ |

For all $\alpha \in\left\{1 \ldots m_{2}\right\}, j \in\{0,1\}$ :
$s_{j}^{\prime}=D_{s k}\left(\tilde{e}_{\alpha}\right)$,
$\mathcal{H}\left(s_{j}^{\prime}\right) \rightarrow r_{j}^{\prime}\left\|\tilde{r}_{j}^{\prime}\right\| \hat{r}_{j}^{\prime}$
Check if $\exists x \in X \quad j \in\{0,1\}$ s.t. :
$t_{j}^{\alpha}=\tilde{r}_{j} \oplus x$, and
$\tilde{e}_{0}^{\alpha}, e_{1}^{\alpha}$, consistent with
$r_{1}^{\prime}, r_{2}^{\prime}, s_{0}^{\prime}, s_{1}^{\prime}, \hat{r}_{0}^{\prime}, \hat{r}_{1}^{\prime}$.

## Preliminaries - the random oracle model

- In the random oracle model (ROM) a specific function is modeled (in the analysis) as a random function
- This analysis is very problematic
- In the theory of crypto proofs in this model are considered as a heuristic
- We describe protocols that are based on the ROM
- There are PSI protocols in the standard model [FNPO4], but they are less efficient.
- We use OT extension
- Can be based on a non-ROM assumption
- But a variant in the ROM is even more efficient

## Public-key based Protocols

## PSI based on Diffie-Hellman

- The Decisional Diffie-Hellman assumption
- Agree on a group $G$, with a generator $g$.
- The assumption: for random $a, b, c$ cannot distinguish ( $g^{a}, g^{b}, g^{a b}$ ) from ( $g^{a}, g^{b}, g^{c}$ )
- (This is a very established assumption in modern crypto)

## PSI based on Diffie-Hellman

- The protocol [M86, HFH99, AES03]:

Compares the two lists
( H is modeled as a random oracle. Security based on DDH) Implementation: very simple; can be based on ellipticcurve crypto; minimal communication.

What else could we want?

## PSI based on Blind RSA [CT10]

- There is also a PSI protocol based on an RSA variant
- The performance should be similar to that of DH based protocols, but
$\circ$ One party does all the hard work $\Rightarrow$ no advantage in the two parties working in parallel
- Cannot be based on elliptic curve crypto

## PSI based on Oblivious Polynomial

## Evaluation [FNP04] (short version)

- (Advantage: proof in the standard model)
- Implemented based on additively homomorphic encryption (Paillier, El Gamal).
- Alice generates the polynomial
$P(x)=\left(x-x_{1}\right)\left(x-x_{2}\right) \cdots\left(x-x_{n}\right)=a_{n} x^{n}+\cdots+a_{1} x+a_{0}$
- Alice sends homomorphic encryptions
$E\left(a_{0}\right), E\left(a_{1}\right), \ldots, E\left(a_{n}\right)$
- $\forall y_{i}$ Bob uses these to evaluate and send $E\left(P\left(y_{i}\right) \cdot r_{i}+y_{i}\right)$
- Implementation: $\mathrm{O}\left(\mathrm{n}^{2}\right)$ exps. Can be reduced to O(nloglogn) using hashing. Too inefficient.

## Generic Protocols

## A circuit based protocol

- There are generic protocols for implementing any functionality expressed as a Binary circuit。GMW, Yao,...
- A naïve circuit uses $\mathrm{n}^{2}$ comparisons of words
- Can we do better?

## A circuit based protocol [HEK12]

- A circuit that has three steps
- Sort: merge two sorted lists using a bitonic merging network [Bat68]. Uses nlog(2n) comparisons.

## A circuit based protocol [HEK12]

- A circuit that has three steps
- Sort: merge two sorted lists using a bitonic merging network [Bat68]. Uses $n \log (2 n)$ comparisons.
- Compare: compare adjacent items. Uses $2 n$ equality checks.
- Shuffle: Randomly shuffle results using a Waxman permutation network [W68], using ~nlog(n) swappings.
- Overall uses $L \cdot(3 n \log n+4 n)$ AND gates. ( $L$ is input length)
- (2/3 of the AND gates are for multiplexers)

# Protocols for Secure Computation are based on Oblivious Transfer (OT) 

## Server

Input:
b
$X_{0}, X_{1}$

Output:
$X_{b}$ nothing
(PSI implies OT)

## Side step: OT extension

There are different OT protocols based on public-key crypto

- [NP01] allows ~1000 OTs per second
[IR89] proved that there is no black-box reduction of OT to one-way functions

OT was believed to be as (in)efficient as public-key crypto

## OT extension

- OT extension runs a small number of "real" OTs, and then uses symmetric-key cryptography to compute from them many OTs [Beaver96,IKNPO3]

## OT extension

- Setting:
- Bob holds $m$ pairs of /-bit messages $\left(x_{i, 0}, x_{i, 1}\right)$
- Alice holds an $m$-bit string $r$ and wants to obtain the value $x_{i, r i}$ in the $i$-th OT
- They perform $k$ "real" OTs on random seeds with reverse roles ( $k=128$ is a symmetric security parameter)
- Alice generates a random $m \times k$ bit matrix $\mathbf{T}$ and masks her choices $r$, using the seeds of the "real" OTs
- The matrix is transposed to be used for the "real" OTs

## Improving OT extension [ALSZ13]

- A lot of time is spent on bit Matrix transpose - improve by using cache efficient alg
- Use parallelization
- Random OT: the two values of the sender are chosen at random
- Cuts communication in half
- Suitable for the GMW protocol and for our protocols!
- Now the bottleneck is essentially the communication

Per OT:
1 \# PRG evaluations

2 \# H evaluations 1

Time distribution for 10M OTs (in 21sec):

## Improving the circuit based PSI of [HEK12]

- GMW uses two OTs per gate; Yao uses four symmetric encryptions.
- Yao was considered much more efficient.
- OT extension makes GMW faster than Yao.
- We noted that $2 / 3$ of the ANDs are for multiplexers
- A single bit chooses between two 32 bit inputs
- For the GMW protocol, this means that instead of using 64 single-bit OTs, can use two OTs with inputs that are 32 bit long.
- Can also base GMW on random-OT.

## Garbled Bloom Filter [DCW13]

## How a Bloom Filter Works

$$
\begin{array}{|l|l|l|l|l|l|l|l|l|l|l|l|l|l|}
\hline 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\
\hline
\end{array}
$$

- A bit array with all zeroes initially
- $k$ hash functions

## How a Bloom Filter Works

## Insertion

- Hash the element using the hash functions, get $k$ indices in the bit array
- Set the bits to 1

## How a Bloom Filter Works

## Lookup

- Hash the element using the hash functions
- If all corresponding bits are 1 , conclude that the element is in the set

## Bloom Filter Analysis

- For a false positive probability of $\varepsilon$, use
- $\mathrm{k}=1 / \log \varepsilon$ hash functions
- m=1.44 kn bits in the filter
- Must set k to be the symmetric security parameter ( $k=128$ or 80 ).
- The resulting filter is longggg... (184-n)

## Short story

- Use a Bloom filter where each entry is a random string
- If $X$ is in the filter, then the XOR of the entries corresponding to $X$ is equal to $X$.
- The parties run an OT per Bloom filter entry (many OTs)
(Long story) Garbled Bloom Filter [DCW13]
- Bob has items $x_{1}, \ldots, x_{n}$.
- Uses a Bloom filter where each entry $i$ is a string $G[i]$, s.t. the xor of the entries to which $x$ is mapped is $x$.
$\circ \oplus_{\mathrm{j}=1 \ldots \mathrm{k}} \mathrm{G}\left[\mathrm{h}_{\mathrm{j}}(\mathrm{x})\right]=\mathrm{x}$.
- Insertion:
- Find an index $t$ such that $G\left[h_{t}(x)\right]$ is unoccupied.
- (The failure probability is equal to the false positive prob $\varepsilon$ )
- Fill all other G[h(x)] entries.
- Set $G\left[h_{t}(x)\right]$ so that the xor of all entries is $x$.

## (Long story) The protocol [DCW13]

- Alice generates a regular Bloom filter A[1...k].
- Bob generates a garbled Bloom filter G[1...k] (using the same hash functions)
- For each entry i in the filter, run an OT
- Alice is the receiver, with input $A[i]$
- Bob is the sender with inputs ( $0, \mathrm{G}[\mathrm{i}]$ )
- Alice checks if $x$ is in the intersection by checking if
$\oplus_{\mathrm{j}=1 \ldots \mathrm{k}} \mathrm{G}\left[\mathrm{h}_{\mathrm{j}}(\mathrm{x})\right]=\mathrm{x}$.
- Alice cannot check this for values not in her input, since the probability of learning all relevant values of G[] is $\varepsilon$.

## Our optimizations

- A complete redesign that can be implemented using random OT extension.
- The protocol
- Uses much less communication
- Becomes completely parallelizable (the original protocol required inserting items one by one)

## Performance

| Optimization | Party | \# bits sent | \# calls to H |
| :---: | :---: | :---: | :---: |
| [DCW13] | Alice | $2 m k$ | $m$ |
|  | Bob | $2 m \lambda$ | $2 m$ |
| [DCW13] + random OT extension of [ALSZ13] | Alice | $m k$ | $m / 2$ |
|  | Bob | $m \lambda$ | $m$ |
| Random Bloom <br> Filter PSI <br> Parallelizable | Alice | $m k$ | $m / 2$ |
|  | Bob | $n \lambda$ | $m / 2$ |
| Bloom filter length: $m=1.44 \cdot 128 \cdot n$ |  |  |  |

## PSI based on OT (a new protocol)

- We first design simple protocols based on OT
- Use OT extension and hashing based constructions to the max

## First step: Private equality test

- Private equality test
- Input: Alice has x, Bob has y. Each is s bits long.
- Output: is $x=y$ ?

## Private equality test

- Alice input: 001 Bob input: 011

## Private equality test

- Alice input: 001 Bob input: 011.
- Random OTs

Alice

Bob

$$
\begin{array}{|l|l|}
\hline \mathrm{R}_{0,0} & \mathrm{R}_{0,1} \\
\hline \mathrm{R}_{1,0} & \mathrm{R}_{1,1} \\
\hline \mathrm{R}_{2,0} & \mathrm{R}_{2,1}
\end{array}
$$

## Private equality test

- Alice input: 001 Bob input: 011
- Random OTs

Alice

Bob

| $R_{0,0}$ | $R_{0,1}$ |
| :--- | :--- |
| $R_{1,0}$ | $R_{1,1}$ |
| $R_{2,0}$ | $R_{2,1}$ |

'Bob sends $\mathrm{R} 0,0 \oplus \mathrm{R} 1,1 \oplus \mathrm{R} 2,1$
'Alice computes $\mathrm{Ro}, 0 \oplus \mathrm{R} 1,0 \oplus \mathrm{R} 2,1$, and compares

## Private set inclusion

- Input: Alice has $x$, Bob has $y_{1}, \ldots, y_{n}$
- Output: is $x$ in $\left\{y_{1}, \ldots, y_{n}\right\}$ ?
- Run $n$ Private Equality Tests in parallel.
- Alice's OT choices for all $\mathrm{y}_{1}, \ldots, \mathrm{y}_{\mathrm{n}}$ are the same
- Run only s random OTs of seeds.
- Use a pseudo-random generator to generate from each seed n strings of length $\lambda$ bits ©
- Send $\lambda n$ bits from Bob to Alice

## Private set intersection

- Input: Alice has $\left\{x_{1}, \ldots, x_{n}\right\}$, Bob has $y_{1}, \ldots, y_{n}$
- Output: Intersection of $\left\{x_{1}, \ldots, x_{n}\right\}$ and $\left\{y_{1}, \ldots, y_{n}\right\}$
- Run n Private Set Inclusion protocols
- Total communication is $\underline{n}^{2} \lambda$ bits
- Communication can be further reduced via hashing

## Hashing

- Suppose each party uses a random hash function H() , (known to both) to hash its n items to n bins.
- Then obviously if Alice and Bob have the same item, both of them map it to the same bin.
- Each bin is expected to have O(1) items
- The items mapped to the bin can be compared using private equality tests, with $O(\lambda)$ communication.
- Overall only $\mathrm{O}(\mathrm{n} \lambda)$ communication.
- The problem
- Some bins have more items
- Must hide how many items were mapped to each bin

## Hashing

- Solution
- Pad each bin with dummy items
- so that all bins are of the size of the most populated bin
- Mapping $n$ items to $n$ bins
- The expected size of a bin is $O(1)$
- The maximum size of a bin is whp O(logn)
- Communication increases by O(logn) to be O(n入logn) $):$

## Hashing

- Mapping n items to about $\mathrm{n} / \operatorname{lnn}$ bins
- The expected size of a bin is $\approx O(\ln n)$
- The maximum size of a bin is (whp) the same
- This is ideal, since we cannot hope to pay less than the expected cost
- Each bin has O(ln n) items. Each item can be represented by $\mathrm{O}(\ln \ln \mathrm{n})$ bits.
- The work per bin is $O(\ln n \cdot \ln \ln n)$
- Total work is $\mathrm{O}(\mathrm{n} / \operatorname{lnn} \cdot \ln \mathrm{n} \cdot \ln \ln \mathrm{n})=\mathrm{O}(\mathrm{n} \cdot \ln \ln \mathrm{n})$

## Other hashing schemes

- Power of two hashing (balanced allocations)
- Cuckoo hashing

Only an asymptotic comparison was previously done

|  | Total \#OTs | OT comm. | Overall Comm. <br> $(M B)$ for $\mathrm{n}=2^{18}$ |
| :--- | :---: | :---: | :---: |
| No hashing | $n s$ | $\mathrm{n}^{2} \lambda$ | 327,808 |
| Simple hashing | 3.7 ns | $\mathrm{n} \lambda$ | 475 |
| Balanced <br> hashing | $2.9 \mathrm{~ns} \ln \ln n$ | $2 \mathrm{n} \lambda$ | 939 |
| Cuckoo hashing | $(2(1+\varepsilon) \mathrm{n}+\operatorname{lnn}) \mathrm{s}$ | $(2+\operatorname{lnn}) \mathrm{n} \lambda$ | 276 |

## Experiments

- No previous "fair" comparison of all protocols
- We used two Intel Core2Quad desk-top PCs with 4 GB RAM, connected via Gigabit LAN
- Inputs are 32 bit long
- Statistical security parameter $\lambda=40$
- Symmetric security parameter 80 or 128
- Gigabit Ethernet

## Results: run time ( $2^{18}$ items)

| Protocol | 80 -bit | 128-bit | Asymptotic |
| :--- | :--- | :--- | :--- |
| DH FFC | 99 | 1224 | 2 n PK |
| DH ECC | 178 | 416 | 2 n PK |
| Blind RSA | 125 | 1982 | 2 n PK |
| Circuit + GMW | 807 | 1304 | 9ns logn sym |
| Optimized GMW | 462 | 762 | 3ns logn sym |
| Garbled Bloom | 72 | 154 | 2 kn sym |
| Optimized G. Bloom | 34 | 68 | $\mathrm{nk} / 2$ sym |
| OT + hashing | 13 | 14 | $\mathrm{~ns} / 4$ sym |

## Results: communication (2 $2^{18}$ items)

| Protocol | 80 -bit | 128-bit | Asymptotic |
| :--- | :--- | :--- | :--- |
| DH FFC | 96 | 192 |  |
| DH ECC | 15 | 26 |  |
| Blind RSA | 67 | 132 |  |
| Circuit + GMW | 14760 | 23400 |  |
| Optimized GMW | 8856 | 14040 |  |
| Garbled Bloom | 866 | 1393 |  |
| Optimized G. Bloom | 290 | 740 |  |
| OT + hashing | 54 | 78 |  |

## DH: run time ( $2^{18}$ items)

| Protocol | 80 -bit | 128-bit | Asymptotic |
| :--- | :--- | :--- | :--- |
| DH FFC | 99 | 1224 | 2 n PK |
| DH ECC | 178 | 416 | 2 n PK |
| Blind RSA | 125 | 1982 | 2 n PK |
| Circuit + GMW | 807 | 1304 | 9ns logn sym |
| Optimized GMW | 462 | 762 | 3ns logn sym |
| Garbled Bloom | 72 | 154 | 2 kn sym |
| Optimized G. Bloom | 34 | 68 | $\mathrm{nk} / 2$ sym |
| OT + hashing | 13 | 14 | $\mathrm{~ns} / 4$ sym |

Pretty good performance!
ECC slower for 80 bit due to quality of the implementation (MIRACL vs. GIMP)

## DH : communication ( $2^{18}$ items)

| Protocol | 80 -bit | 128-bit | Asymptotic |
| :--- | :--- | :--- | :--- |
| DH FFC | 96 | 192 |  |
| DH ECC | 15 | 26 |  |
| Blind RSA | 67 | 132 |  |
| Circuit + GMW | 14760 | 23400 |  |
| Optimized GMW | 8856 | 14040 |  |
| Garbled Bloom | 866 | 1393 |  |
| Optimized G. Bloom | 290 | 740 |  |
| OT + hashing | 54 | 78 |  |

ECC has the best communication overhead of all protocols

## Blind RSA: run time ( $2^{18}$ items)

| Protocol | 80 -bit | 128-bit | Asymptotic |
| :--- | :--- | :--- | :--- |
| DH FFC | 99 | 1224 | 2 n PK |
| DH ECC | 178 | 416 | 2 n PK |
| Blind RSA | 125 | 1982 | 2 n PK |
| Circuit + GMW | 809 | 1306 | 9ns logn sym |
| Optimized GMW | 465 | 764 | 3ns logn sym |
| Garbled Bloom | 72 | 154 | 2 kn sym |
| Optimized G. Bloom | 32 | 66 | nk/2 sym |
| OT + hashing | 36 | 46 | ns/4 sym |

For 80 bit security, faster than a circuit (but not than DH)
Asymmetric work load between the parties

## DH: communication (2 $2^{18}$ items)

| Protocol | 80 -bit | 128-bit | Asymptotic |
| :--- | :--- | :--- | :--- |
| DH FFC | 96 | 192 |  |
| DH ECC | 15 | 26 |  |
| Blind RSA | 67 | 132 |  |
| Circuit + GMW | 9507 | 15072 |  |
| Optimized GMW | 3790 | 5964 |  |
| Garbled Bloom | 866 | 1393 |  |
| Optimized G. Bloom | 290 | 740 |  |
| OT + hashing | 176 | 276 |  |

## Circuit: run time ( $2^{18}$ items)

| Protocol | 80 -bit | 128-bit | Asymptotic |
| :--- | :--- | :--- | :--- |
| DH FFC | 99 | 1224 | 2 n PK |
| DH ECC | 178 | 416 | 2 n PK |
| Blind RSA | 125 | 1982 | 2 n PK |
| Circuit + GMW | 807 | 1304 | 9ns logn sym |
| Optimized GMW | 462 | 762 | 3ns logn sym |
| Garbled Bloom | 72 | 154 | 2 kn sym |
| Optimized G. Bloom | 34 | 68 | $\mathrm{nk} / 2$ sym |
| OT + hashing | 13 | 14 | $\mathrm{~ns} / 4$ sym |

The basic protocol is the most inefficient
Our optimizations saved more than $40 \%$ (over standard OT extension)
The result is comparable to PK based protocols
The advantage is the generality of a circuit based solution.

## Circuit: communication ( $2^{18}$ items)

| Protocol | 80 -bit | 128 -bit | Asymptotic |
| :--- | :--- | :--- | :--- |
| DH FFC | 96 | 192 |  |
| DH ECC | 15 | 26 |  |
| Blind RSA | 67 | 132 |  |
| Circuit + GMW | 14760 | 23400 |  |
| Optimized GMW | 8856 | 14040 |  |
| Garbled Bloom | 866 | 1393 |  |
| Optimized G. Bloom | 290 | 740 |  |
| OT + hashing | 54 | 78 |  |

Highest communication overhead

## Bloom + OT: run time ( $2^{18}$ items)

| Protocol | 80 -bit | 128-bit | Asymptotic |
| :--- | :--- | :--- | :--- |
| DH FFC | 99 | 1224 | 2 n PK |
| DH ECC | 178 | 416 | 2 n PK |
| Blind RSA | 125 | 1982 | 2 n PK |
| Circuit + GMW | 807 | 1304 | 9ns logn sym |
| Optimized GMW | 462 | 762 | 3ns logn sym |
| Garbled Bloom | 72 | 154 | 2 kn sym |
| Optimized G. Bloom | 34 | 68 | $\mathrm{nk} / 2$ sym |
| OT + hashing | 13 | 14 | $\mathrm{~ns} / 4$ sym |

The optimized Bloom protocol is 55\% faster than the basic Bloom protocol The new OT+hashing protocol even faster Overall, OT protocols are the fastest.

## Bloom + OT: run time ( $2^{18}$ items)

| Protocol | 80 -bit | 128-bit | Asymptotic |
| :--- | :--- | :--- | :--- |
| DH FFC | 99 | 1224 | 2 n PK |
| DH ECC | 178 | 416 | 2 n PK |
| Blind RSA | 125 | 1982 | 2 n PK |
| Circuit + GMW | 807 | 1304 | 9ns logn sym |
| Optimized GMW | 462 | 762 | 3ns logn sym |
| Garbled Bloom | 72 | 154 | 2 kn sym |
| Optimized G. Bloom | 34 | 68 | nk/2 sym |
| OT + hashing | 13.5 | 13.8 | $\mathrm{~ns} / 4$ sym |

Our OT based protocol is unaffected by the security parameter (due to the use of symmetric crypto + communication efficiency)

## Bloom + OT: communication ( $2^{18}$ items)

| Protocol | 80 -bit | 128-bit | Asymptotic |
| :--- | :--- | :--- | :--- |
| DH FFC | 96 | 192 |  |
| DH ECC | 15 | 26 |  |
| Blind RSA | 67 | 132 |  |
| Circuit + GMW | 14760 | 23400 |  |
| Optimized GMW | 8856 | 14040 |  |
| Garbled Bloom | 866 | 1393 |  |
| Optimized G. Bloom | 290 | 740 |  |
| OT + hashing | 54 | 78 |  |

The optimized Bloom protocol reduces communication by 45\%-70\%. OT protocol has the best communication, except for the ECC-DH protocol.

## Using four threads ( $2^{18}$ items)

| Protocol | Single thread 128-bit | Four threads | Speedup |
| :--- | :--- | :--- | :---: |
| DH FFC | 1224 | 320 | $\times 3.8$ |
| DH ECC | 416 |  |  |
| Blind RSA | 1982 |  |  |
| Circuit + GMW | 1364 | 401 | $\times 1.9$ |
| Optimized GMW | 762 |  | $\times 2.6$ |
| Garbled Bloom | 154 | 26 | $\times 2.8$ |
| Optimized Bloom | 68 | 5 |  |
| OT + hashing | 14 |  |  |

DH and OT protocols benefit most from parallelization. Performance of circuit protocol depends more on communication.

Throughput: about a million items per 20 sec .

## Communication effect on runtime ( $2^{16}$ items)

| Protocol | Gigabit LAN (1000/0.2) | $\begin{aligned} & \hline 802.11 \mathrm{~g} \\ & (54 / 0.2) \end{aligned}$ | Intracountry $(25 / 10)$ | Intracountry $(10 / 50)$ | $\begin{aligned} & \text { HDSPA } \\ & (3.6 / 500) \end{aligned}$ |
| :---: | :---: | :---: | :---: | :---: | :---: |
| DH ECC | 104 | 105 | 108 | 112 | 116 |
| Optimized GMW | $1: 2.2$ |  | $1: 2.5$ |  | 5311 |
| Optimized Bloom | 17 | $: 2.2^{37}$ | $71 \quad$ | $2.3^{165}$ | 445 |
| OT + hashing | 3.8 | $1.8{ }^{5}$ | 8.81 | 2.623 | 78 |

DH is unaffected by the communication channel OT+hashing is still the most efficient protocol.

## Conclusions

- Set intersection can be efficiently applied to very large input sets
- Different settings require different protocols
- Communication
- Generality
- Input lengths
