Abstract. Frame and anti-frame rules have been proposed as proof rules for modular reasoning about programs. Frame rules allow one to hide irrelevant parts of the state during verification, whereas the anti-frame rule allows one to hide local state from the context. We give the first sound model for Charguéraud and Pottier’s type and capability system including both frame and anti-frame rules. The model is a possible worlds model based on the operational semantics and step-indexed heap relations, and the worlds are constructed as a recursively defined predicate on a recursively defined metric space.

We also extend the model to account for Pottier’s *generalized* frame and anti-frame rules, where invariants are generalized to *families* of invariants indexed over pre-orders. This generalization enables reasoning about some (locally) monotonic uses of local state.

1 Introduction

Reasoning about higher-order stateful programs is notoriously difficult, and often involves the need to track aliasing information. A particular line of work that addresses this point are substructural type systems with regions, capabilities and singleton types [2, 8, 9]. In this context, Pottier [13] presented the anti-frame rule as a proof rule for hiding invariants on encapsulated state: the description of a piece of mutable state that is *local* to a procedure can be removed from the procedure’s external interface (expressed in the type system). The benefits of hiding invariants on local state include simpler interface specifications, simpler reasoning about client code, and fewer restrictions on the procedure’s use because potential aliasing is reduced. Thus, in combination with frame rules that allow the irrelevant parts of the state to be hidden during verification, the anti-frame rule provides an important ingredient for modular reasoning about programs.

Essentially, the frame and anti-frame rules exploit the fact that programs cannot access non-local state directly. However, in an ML-like language with higher-order procedures and the possibility of call-backs, the dependencies on

^{*} A preliminary version of this article has been presented at the 7th Workshop on Fixed Points in Computer Science, FICS 2010.

non-local state can be complex; consequently, the soundness of frame and anti-frame rules is anything but obvious.

Pottier [13] sketched a soundness proof for the anti-frame rule by a progress and preservation argument, which rests on assumptions about the existence of certain recursively defined types and capabilities. (He is currently formalizing the details in Coq.) More recently, Birkedal et al. [6] developed a step-indexed model of Charguéraud and Pottier’s type and capability system with higher-order frame rules, but without the anti-frame rule. This was a Kripke model in which capabilities are viewed as assertions (on heaps) that are indexed over recursively defined worlds: intuitively, these worlds are used to represent the invariants that have been added by the frame rules.

Proving soundness of the anti-frame rule requires a refinement of this idea, as one needs to know that additional invariants do not invalidate the invariants on local state which have been hidden by the anti-frame rule. This requirement can be formulated in terms of a monotonicity condition for the world-indexed assertions, using an order on the worlds that is induced by invariant extension [17]. (The fact that ML-style untracked references can be encoded from strong references with the anti-frame rule [13] also indicates that a monotonicity condition is required: Kripke models of ML-style references involve monotonicity in the worlds [7, 1].) More precisely, in the presence of the anti-frame rule, it turns out that the recursive domain equation for the worlds involves monotonic functions with respect to an order relation on worlds, and that this order is specified using the isomorphism of the recursive world solution itself. This circularity means that the standard existence theorems, in particular the one used in [6], cannot be applied to define the worlds. Thus Schwinghammer et al. [17], who considered a separation logic variant of the anti-frame rule for a simple language (without higher-order functions, and untyped), had to give the solution to a similar recursive domain equation by a laborious inverse-limit construction.

In the present paper we develop a new model of Charguéraud and Pottier’s system, which can also be used to show soundness of the anti-frame rule. Moreover, we show how to extend our model to show soundness of Pottier’s *generalized* frame and anti-frame rules, which allow hiding of *families* of invariants [14]. The new model is a non-trivial extension of the earlier work because, as pointed out above, the anti-frame rule is the “source” of a circular monotonicity requirement.

Our approach can loosely be described as a metric space analogue of Pitts’ approach to relational properties of domains [12] and thus consists of two steps. First, we consider a recursive metric space domain equation without any monotonicity requirement, for which we obtain a solution by appealing to a standard existence theorem. Second, we carve out a suitable subset of what might be called *hereditarily monotonic* functions. We show how to define this recursively specified subset as a fixed point of a suitable operator. The resulting subset of monotonic functions is, however, not a solution to the original recursive domain equation; hence we verify that the semantic constructions used to justify the anti-frame rule in [17] suitably restrict to the recursively defined subset of hereditarily monotonic functions. This results in a considerably simpler model

construction than the earlier one in *loc. cit.* We show that our approach scales by extending the model to also allow for hiding of families of invariants, and using it to prove the soundness of Pottier’s generalized frame and anti-frame rules [14].

Contributions. In summary, the contributions of this paper are (1) the development of a considerably simpler model of recursive worlds for showing the soundness of the anti-frame rule; (2) the use of this model to give the first soundness proof of the anti-frame rule in the expressive type and capability system of Charguéraud and Pottier; and (3) the extension of the model to include hiding of families of invariants, and showing the soundness of generalized frame and anti-frame rules. Moreover, at a conceptual level, we augment our earlier approach to constructing (step-indexed) recursive possible worlds based on a programming language’s operational semantics via metric spaces [6] by a further tool, *viz.*, defining worlds as recursive subsets of recursive metric spaces.

Outline. In the next section we give a brief overview of Charguéraud and Pottier’s type and capability system [8, 13] with higher-order frame and anti-frame rules. Section 3 summarizes some background on ultrametric spaces and presents the construction of a set of hereditarily monotonic recursive worlds. The worlds thus constructed are then used (Section 4) to give a model of the type and capability system. Finally, in Section 5 we show how to extend the model to also prove soundness of the generalized frame and anti-frame rules.

For space reasons, many details are relegated to a technical appendix.

2 A Calculus of Capabilities

Syntax and operational semantics. We consider a standard call-by-value, higher-order language with general references, sum and product types, and polymorphic and recursive types. For concreteness, the following grammar gives the syntax of values and expressions, keeping close to the notation of [8, 13]:

$$\begin{aligned} v &::= x \mid () \mid \text{inj}^i v \mid (v_1, v_2) \mid \text{fun } f(x)=t \mid l \\ t &::= v \mid (vt) \mid \text{case}(v_1, v_2, v) \mid \text{proj}^i v \mid \text{ref } v \mid \text{get } v \mid \text{set } v \end{aligned}$$

Here, the term $\text{fun } f(x)=t$ stands for the recursive procedure f with body t , and locations l range over a countably infinite set Loc . The operational semantics is given by a relation $(t \mid h) \mapsto (t' \mid h')$ between configurations that consist of a (closed) expression t and a heap h . We take a heap h to be a finite map from locations to closed values, we use the notation $h \# h'$ to indicate that two heaps h, h' have disjoint domains, and we write $h \cdot h'$ for the union of two such heaps. By Val we denote the set of closed values.

Types. Charguéraud and Pottier’s type system uses *capabilities*, *value types*, and *memory types*, as summarized in Figure 1. A capability C describes a heap property, much like the assertions of a Hoare-style program logic. For instance,

Variables	$\xi ::= \alpha \mid \beta \mid \gamma \mid \sigma$
Capabilities	$C ::= C \otimes C \mid \emptyset \mid C * C \mid \{\sigma : \theta\} \mid \exists \sigma. C \mid \gamma \mid \mu \gamma. C \mid \forall \xi. C$
Value types	$\tau ::= \tau \otimes C \mid 0 \mid 1 \mid \text{int} \mid \tau + \tau \mid \tau \times \tau \mid \chi \rightarrow \chi \mid [\sigma] \mid \alpha \mid \mu \alpha. \tau \mid \forall \xi. \tau$
Memory types	$\theta ::= \theta \otimes C \mid \tau \mid \theta + \theta \mid \theta \times \theta \mid \text{ref } \theta \mid \theta * C \mid \exists \sigma. \theta \mid \beta \mid \mu \beta. \theta \mid \forall \xi. \theta$
Computation types	$\chi ::= \chi \otimes C \mid \tau \mid \chi * C \mid \exists \sigma. \chi$
Value contexts	$\Delta ::= \Delta \otimes C \mid \emptyset \mid \Delta, x : \tau$
Linear contexts	$\Gamma ::= \Gamma \otimes C \mid \emptyset \mid \Gamma, x : \chi \mid \Gamma * C$

Fig. 1. Capabilities and types

$\{\sigma : \text{ref int}\}$ asserts that σ is a valid location that contains an integer value. More complex assertions can be built by separating conjunctions $C_1 * C_2$ and universal and existential quantification over names σ . Value types τ classify values; they include base types, singleton types $[\sigma]$, and are closed under products, sums, and universal quantification. *Memory types* (and the subset of computation types χ) describe the result of computations. They extend the value types by a type of references, and also include all types of the form $\exists \vec{\sigma}. \tau * C$ which describe both the value and heap that result from the evaluation of an expression. Arrow types (which are value types) have the form $\chi_1 \rightarrow \chi_2$ and thus, like the pre- and post-conditions of a triple in Hoare logic, make explicit which part of the heap is accessed and modified by a procedure call. We allow recursive capabilities, value types, and memory types, resp., provided the recursive definition is formally contractive, i.e., the recursion must go through a type constructor such as \rightarrow .

Since Charguéraud and Pottier’s system tracks aliasing, so-called strong (i.e., non-type preserving) updates are permitted: a possible type for such an update operation is $\forall \sigma, \sigma'. ([\sigma] \times [\sigma']) * \{\sigma : \text{ref } \tau\} \rightarrow \mathbf{1} * \{\sigma : \text{ref } [\sigma']\}$. Here, the argument to the procedure is a pair consisting of a location (named σ) and the value to be stored (named σ'), and the location is assumed to be allocated in the initial heap (and store a value of some type τ). The result of the procedure is unit, but as a side-effect σ' will be stored at the location σ .

Frame and anti-frame rules. Each of the syntactic categories is equipped with an *invariant extension* operation, $\cdot \otimes C$. Intuitively, this operation conjoins C to the domain and codomain of every arrow type that occurs within its left hand argument, which means that the capability C is preserved by all procedures of this type. This intuition is made precise by regarding capabilities and types modulo a structural equivalence which subsumes the “distribution axioms” for \otimes that are used to express generic higher-order frame rules [5]. The two key cases of the structural equivalence are the distribution axioms for arrow types, $(\chi_1 \rightarrow \chi_2) \otimes C = (\chi_1 \otimes C * C) \rightarrow (\chi_2 \otimes C * C)$, and for successive extensions, $(\chi \otimes C_1) \otimes C_2 = \chi \otimes (C_1 \circ C_2)$ where the derived operation $C_1 \circ C_2$ abbreviates the conjunction $(C_1 \otimes C_2) * C_2$.

There are two typing judgements, $x_1 : \tau_1, \dots, x_n : \tau_n \vdash v : \tau$ for values, and $x_1 : \chi_1, \dots, x_n : \chi_n \Vdash t : \chi$ for expressions. The latter is similar to a Hoare triple

where (the separating conjunction of) χ_1, \dots, χ_n serves as a precondition and χ as a postcondition. This view provides some intuition for the following “shallow” and “deep” frame rules, and for the (essentially dual) anti-frame rule:

$$\begin{array}{c}
[SF] \frac{\Gamma \Vdash t : \chi}{\Gamma * C \Vdash t : \chi * C} \qquad [DF] \frac{\Gamma \Vdash t : \chi}{(\Gamma \otimes C) * C \Vdash t : (\chi \otimes C) * C} \\
[AF] \frac{\Gamma \otimes C \Vdash t : (\chi \otimes C) * C}{\Gamma \Vdash t : \chi}
\end{array} \tag{1}$$

As in separation logic, the frame rules can be used to add a capability C (which might assert the existence of an integer reference, say) as an invariant to a specification $\Gamma \Vdash t : \chi$, which is useful for local reasoning. The difference between the shallow variant $[SF]$ and the deep variant $[DF]$ is that the former adds C only on the top-level, whereas the latter also extends all arrow types nested inside Γ and χ , via $\cdot \otimes C$. While the frame rules can be used to reason about certain forms of information hiding [5], the anti-frame rule expresses a hiding principle more directly: the capability C can be removed from the specification if C is an invariant that is established by t , expressed by $\cdot * C$, and that is guaranteed to hold whenever control passes from t to the context and back, expressed by $\cdot \otimes C$.

Pottier [13] illustrates the anti-frame rule by a number of applications. One of these is a fixed-point combinator implemented by means of “Landin’s knot”, i.e., recursion through heap. Every time the combinator is called with a functional $f : (\chi_1 \rightarrow \chi_2) \rightarrow (\chi_1 \rightarrow \chi_2)$, a new reference cell σ is allocated in order to set up the recursion required for the resulting fixed point $fix f$. Subsequent calls to $fix f$ still rely on this cell, and in Charguéraud and Pottier’s system this is reflected in the type $(\chi_1 \rightarrow \chi_2) \otimes I$ of $fix f$, where the capability $I = \{\sigma : \text{ref } (\chi_1 \rightarrow \chi_2) \otimes I\}$ describes the cell σ after it has been initialized. However, the anti-frame rule allows one to hide the existence of σ , and leads to a purely functional interface of the fixed point combinator. In particular, after hiding I , $fix f$ has the much simpler type $(\chi_1 \rightarrow \chi_2)$, which means that we can reason about aliasing and type safety of programs that *use* the fixed-point combinator without considering the reference cells used internally by that combinator.

3 Hereditarily Monotonic Recursive Worlds

Intuitively, capabilities describe heaps. A key idea of the model that we present next is that capabilities (as well as types and type contexts) are parameterized by invariants – this will make it easy to interpret the invariant extension operation \otimes , as in [15, 17]. That is, rather than interpreting a capability C directly as a set of heaps, we interpret it as a function $\llbracket C \rrbracket : W \rightarrow \text{Pred}(\text{Heap})$ that maps “invariants” from W to sets of heaps. Intuitively, invariant extension of C is then interpreted by applying $\llbracket C \rrbracket$ to the given invariant. In contrast, a simple interpretation of C as a set of heaps would not contain enough information to determine the meaning of every invariant extension of C .

The question is now what the set W of invariants should be. As the frame and anti-frame rules in (1) indicate, invariants are in fact arbitrary capabilities, so W should be the set used to interpret capabilities. But, as we just saw, capabilities should be interpreted as functions from W to $Pred(Heap)$. Thus, we are led to consider a Kripke model where the worlds are *recursively defined*: to a first approximation, we need a solution to the equation

$$W = W \rightarrow Pred(Heap) . \quad (2)$$

In fact, we will also need to consider a preorder on W and ensure that the interpretation of capabilities and types is *monotonic*. We will find a solution to a suitable variant of (2) using ultrametric spaces.

Ultrametric spaces. We recall some basic definitions and results about ultrametric spaces; for a less condensed introduction to ultrametric spaces we refer to [18]. A *1-bounded ultrametric space* (X, d) is a metric space where the distance function $d : X \times X \rightarrow \mathbb{R}$ takes values in the closed interval $[0, 1]$ and satisfies the “strong” triangle inequality $d(x, y) \leq \max\{d(x, z), d(z, y)\}$. A metric space is *complete* if every Cauchy sequence has a limit. A function $f : X_1 \rightarrow X_2$ between metric spaces (X_1, d_1) , (X_2, d_2) is *non-expansive* if $d_2(f(x), f(y)) \leq d_1(x, y)$ for all $x, y \in X_1$. It is *contractive* if there exists some $\delta < 1$ such that $d_2(f(x), f(y)) \leq \delta \cdot d_1(x, y)$ for all $x, y \in X_1$. By the Banach fixed point theorem, every contractive function $f : X \rightarrow X$ on a complete and non-empty metric space (X, d) has a (unique) fixed point. By multiplication of the distances of (X, d) with a non-negative factor $\delta < 1$, one obtains a new ultrametric space, $\delta \cdot (X, d) = (X, d')$ where $d'(x, y) = \delta \cdot d(x, y)$.

The complete, 1-bounded, non-empty, ultrametric spaces and non-expansive functions between them form a Cartesian closed category $CBUlt_{ne}$. Products are given by the set-theoretic product where the distance is the maximum of the componentwise distances. The exponential $(X_1, d_1) \rightarrow (X_2, d_2)$ has the set of non-expansive functions from (X_1, d_1) to (X_2, d_2) as underlying set, and the distance function is given by $d_{X_1 \rightarrow X_2}(f, g) = \sup\{d_2(f(x), g(x)) \mid x \in X_1\}$.

The notation $x \stackrel{n}{=} y$ means that $d(x, y) \leq 2^{-n}$. Each relation $\stackrel{n}{=}$ is an equivalence relation because of the ultrametric inequality; we refer to this relation as “ n -equality.” Since the distances are bounded by 1, $x \stackrel{0}{=} y$ always holds, and the n -equalities become finer as n increases. If $x \stackrel{n}{=} y$ holds for all n then $x = y$.

Uniform predicates, worlds and world extension. Let (A, \sqsubseteq) be a partially ordered set. An *upwards closed, uniform predicate* on A is a subset $p \subseteq \mathbb{N} \times A$ that is downwards closed in the first and upwards closed in the second component: if $(k, a) \in p$, $j \leq k$ and $a \sqsubseteq b$, then $(j, b) \in p$. We write $UPred(A)$ for the set of all such predicates on A , and we define $p_{[k]} = \{(j, a) \mid j < k\}$. Note that $p_{[k]} \in UPred(A)$. We equip $UPred(A)$ with the distance function $d(p, q) = \inf\{2^{-n} \mid p_{[n]} = q_{[n]}\}$, which makes $(UPred(A), d)$ an object of $CBUlt_{ne}$.

In our model, we use $UPred(A)$ with the following concrete instances for the partial order (A, \sqsubseteq) : (1) *heaps* $(Heap, \sqsubseteq)$, where $h \sqsubseteq h'$ iff $h' = h \cdot h_0$ for

some $h_0 \# h$, (2) *values* (Val, \sqsubseteq) , where $u \sqsubseteq v$ iff $u = v$, and (3) *stateful values* $(Val \times Heap, \sqsubseteq)$, where $(u, h) \sqsubseteq (v, h')$ iff $u = v$ and $h \sqsubseteq h'$. We also use variants of the latter two instances where the set Val is replaced by the set of value substitutions, Env , and by the set of closed expressions, Exp . On $UPred(Heap)$, ordered by subset inclusion, we have a complete Heyting BI algebra structure [4]. Below we only need the separating conjunction and its unit I , given by

$$p_1 * p_2 = \{(k, h) \mid \exists h_1, h_2. h = h_1 \cdot h_2 \wedge (k, h_1) \in p_1 \wedge (k, h_2) \in p_2\}$$

and $I = \mathbb{N} \times Heap$. Still, this observation on $UPred(Heap)$ suggests that Pottier and Charguéraud's system could be extended to a full-blown program logic.

It is well-known that one can solve recursive domain equations in $CBUlt_{ne}$ by an adaptation of the inverse-limit method from classical domain theory [3]. In particular, with regard to the domain equation (2) above:

Theorem 1. *There exists a unique (up to isomorphism) $(X, d) \in CBUlt_{ne}$ such that $\iota: \frac{1}{2} \cdot X \rightarrow UPred(Heap) \cong X$.*

Using the pointwise lifting of separating conjunction to $\frac{1}{2} \cdot X \rightarrow UPred(Heap)$ we define a *composition operation* on X , which reflects the syntactic abbreviation $C_1 \circ C_2 = C_1 \otimes C_2 * C_2$ of conjoining C_1 and C_2 and additionally applying an invariant extension to C_1 . Formally, $\circ: X \times X \rightarrow X$ is a non-expansive operation that for all $p, q, x \in X$ satisfies

$$\iota^{-1}(p \circ q)(x) = \iota^{-1}(p)(q \circ x) * \iota^{-1}(q)(x),$$

and which can be defined by an easy application of Banach's fixed point theorem as in [15]. One can show that this operation is associative and has a left and right unit given by $emp = \iota(\lambda w. I)$; thus (X, \circ, emp) is a monoid in $CBUlt_{ne}$.

Then, using \circ we define an *extension operation* $\otimes: Y^{(1/2 \cdot X)} \times X \rightarrow Y^{(1/2 \cdot X)}$ for any $Y \in CBUlt_{ne}$ by $(f \otimes x)(x') = f(x \circ x')$. Not going into details here, let us remark that \otimes is the semantic counterpart to the syntactic invariant extension, and thus plays a key role in the model. However, for Pottier's anti-frame rule we also need to ensure that specifications are not invalidated by invariant extension. This requirement is stated via monotonicity, as we discuss next.

Relations on ultrametric spaces and hereditarily monotonic worlds.

As a consequence of the fact that \circ defines a monoid structure on X there is an induced preorder on X : $x \sqsubseteq y \Leftrightarrow \exists x_0. y = x \circ x_0$.

For modelling the anti-frame rule, we aim for a set of worlds similar to $X \cong \frac{1}{2} \cdot X \rightarrow UPred(Heap)$ but where the function space consists of the non-expansive functions that are additionally monotonic, with respect to the order induced by \circ on X and with respect to set inclusion on $UPred(Heap)$:

$$(W, \sqsubseteq) \cong \frac{1}{2} \cdot (W, \sqsubseteq) \rightarrow_{mon} (UPred(Heap), \sqsubseteq). \quad (3)$$

Because the definition of the order \sqsubseteq (induced by \circ) already uses the isomorphism between left-hand and right-hand side, and because the right-hand side

depends on the order for the monotonic function space, the standard existence theorems for solutions of recursive domain equations do not appear to apply to (3). Previously we have constructed a solution to this equation explicitly as inverse limit of a suitable chain of approximations [17]. We show in the following that we can alternatively carve out from X a suitable subset of what we call *hereditarily monotonic* functions. This subset needs to be defined recursively.

Let \mathcal{R} be the collection of all non-empty and closed relations $R \subseteq X$. We set

$$R_{[n]} \stackrel{\text{def}}{=} \{y \mid \exists x \in X. x \stackrel{n}{=} y \wedge x \in R\}.$$

for $R \in \mathcal{R}$. Thus, $R_{[n]}$ is the set of all points within distance 2^{-n} of R . Note that $R_{[n]} \in \mathcal{R}$. In fact, $\emptyset \neq R \subseteq R_{[n]}$ holds by the reflexivity of n -equality, and if $(y_k)_{k \in \mathbb{N}}$ is a sequence in $R_{[n]}$ with limit y in X then $d(y_k, y) \leq 2^{-n}$ must hold for some k , i.e., $y_k \stackrel{n}{=} y$. So there exists $x \in X$ with $x \in R$ and $x \stackrel{n}{=} y_k$, and hence by transitivity $x \stackrel{n}{=} y$ which then gives $\lim_n y_n \in R_{[n]}$.

We make some further observations that follow from the properties of n -equality on X . First, $R \subseteq S$ implies $R_{[n]} \subseteq S_{[n]}$ for any $R, S \in \mathcal{R}$. Moreover, using the fact that the n -equalities become increasingly finer it follows that $(R_{[m]})_{[n]} = R_{[\min(m, n)]}$ for all $m, n \in \mathbb{N}$, so in particular each $(\cdot)_{[n]}$ is a closure operation on \mathcal{R} . As a consequence, we have $R \subseteq \dots \subseteq R_{[n]} \subseteq \dots \subseteq R_{[1]} \subseteq R_{[0]}$. By the 1-boundedness of X , $R_{[0]} = X$ for all $R \in \mathcal{R}$. Finally, $R = S$ if and only if $R_{[n]} = S_{[n]}$ for all $n \in \mathbb{N}$.

Proposition 2. *Let $d : \mathcal{R} \times \mathcal{R} \rightarrow \mathbb{R}$ be defined by $d(R, S) = \inf \{2^{-n} \mid R_{[n]} = S_{[n]}\}$. Then (\mathcal{R}, d) is a complete, 1-bounded, non-empty ultrametric space. The limit of a Cauchy chain $(R_n)_{n \in \mathbb{N}}$ with $d(R_n, R_{n+1}) \leq 2^{-n}$ is given by $\bigcap_n (R_n)_{[n]}$, and in particular $R = \bigcap_n R_{[n]}$ for any $R \in \mathcal{R}$.*

We will now define the set of hereditarily monotonic functions W as a recursive predicate on the space X . Let the function $\Phi : \mathcal{P}(X) \rightarrow \mathcal{P}(X)$ on subsets of X be given by $\Phi(R) = \{\iota(p) \mid \forall x, x_0 \in R. p(x) \subseteq p(x \circ x_0)\}$.

Lemma 3. *Φ restricts to a contractive function on \mathcal{R} : if $R \in \mathcal{R}$ then $\Phi(R)$ is non-empty and closed, and $R \stackrel{n}{=} S$ implies $\Phi(R) \stackrel{n+1}{=} \Phi(S)$.*

While the proof of this lemma is not particularly difficult, we include it here to illustrate the kind of reasoning that is involved.

Proof. It is clear that $\Phi(R) \neq \emptyset$ since $\iota(p) \in \Phi(R)$ for every constant function p from $\frac{1}{2} \cdot X$ to $UPred(Heap)$. Limits of Cauchy chains in $\frac{1}{2} \cdot X \rightarrow UPred(Heap)$ are given pointwise, hence $(\lim_n p_n)(x) \subseteq (\lim_n p_n)(x \circ x_0)$ holds for all Cauchy chains $(p_n)_{n \in \mathbb{N}}$ in $\Phi(R)$ and all $x, x_0 \in R$. This proves $\Phi(R) \in \mathcal{R}$.

We now show that Φ is contractive. To this end, let $n \geq 0$ and assume $R \stackrel{n}{=} S$. Let $\iota(p) \in \Phi(R)_{[n+1]}$. We must show that $\iota(p) \in \Phi(S)_{[n+1]}$. By definition of the closure operation there exists $\iota(q) \in \Phi(R)$ such that p and q are $(n+1)$ -equal. Set $r(w) = q(w)_{[n+1]}$. Then r and p are also $(n+1)$ -equal, hence it suffices to show that $\iota(r) \in \Phi(S)$. To establish the latter, let $w_0, w_1 \in S$ be arbitrary. By

the assumption that R and S are n -equal there exist elements $w'_0, w'_1 \in R$ such that $w'_0 \stackrel{n}{\cong} w_0$ and $w'_1 \stackrel{n}{\cong} w_1$ in holds X , or equivalently, such that w'_0 and w_0 as well as w'_1 and w_1 are $(n+1)$ -equal in $\frac{1}{2} \cdot X$. By the non-expansiveness of \circ , this implies that also $w'_0 \circ w'_1$ and $w_0 \circ w_1$ are $(n+1)$ -equal in $\frac{1}{2} \cdot X$. Since

$$q(w_0) \stackrel{n+1}{\cong} q(w'_0) \subseteq q(w'_0 \circ w'_1) \stackrel{n+1}{\cong} q(w_0 \circ w_1)$$

holds by the non-expansiveness of q and the assumption that $\iota(q) \in \Phi(R)$, we obtain the required inclusion $r(w_0) \subseteq r(w_0 \circ w_1)$ by definition of r . \square

By Proposition 2 and the Banach theorem we can now define the hereditarily monotonic functions W as the uniquely determined fixed point of Φ , for which

$$w \in W \Leftrightarrow \exists p. w = \iota(p) \wedge \forall w, w_0 \in W. p(w) \subseteq p(w \circ w_0).$$

Note that W thus constructed does not quite satisfy (3). We do not have an isomorphism between W and the non-expansive and monotonic functions from W (viewed as an ultrametric space itself), but rather between W and all functions from X that *restrict* to monotonic functions whenever applied to hereditarily monotonic arguments. Keeping this in mind, we abuse notation and write

$$\begin{aligned} \frac{1}{2} \cdot W &\rightarrow_{\text{mon}} \text{UPred}(A) \\ &\stackrel{\text{def}}{=} \{p : \frac{1}{2} \cdot X \rightarrow \text{UPred}(A) \mid \forall w_1, w_2 \in W. p(w_1) \subseteq p(w_1 \circ w_2)\}. \end{aligned}$$

Then, for our particular application of interest, we also have to ensure that all the operations restrict appropriately (*cf.* Section 4 below). Here, as a first step, we show that the composition operation \circ restricts to W . In turn, this means that the \otimes operator restricts accordingly: if $w \in W$ and p is in $\frac{1}{2} \cdot W \rightarrow_{\text{mon}} \text{UPred}(A)$ then so is $p \otimes w$.

Lemma 4. *For all $n \in \mathbb{N}$, if $w_1, w_2 \in W$ then $w_1 \circ w_2 \in W_{[n]}$. In particular, since $W = \bigcap_n W_{[n]}$ it follows that $w_1, w_2 \in W$ implies $w_1 \circ w_2 \in W$.*

Proof. The proof is by induction on n . The base case is immediate as $W_{[0]} = X$. Now suppose $n > 0$ and let $w_1, w_2 \in W$; we must prove that $w_1 \circ w_2 \in W_{[n]}$. Let w'_1 be such that $\iota^{-1}(w'_1)(w) = \iota^{-1}(w_1)(w)_{[n]}$. Observe that $w'_1 \in W$, that w'_1 and w_1 are n -equal, and that w'_1 is such that n -equality of w, w' in $\frac{1}{2} \cdot X$ already implies $\iota^{-1}(w'_1)(w) = \iota^{-1}(w'_1)(w')$. Since w'_1 and w_1 are n -equivalent, the non-expansiveness of the composition operation implies $w_1 \circ w_2 \stackrel{n}{\cong} w'_1 \circ w_2$. Thus it suffices to show that $w'_1 \circ w_2 \in W = \Phi(W)$. To see this, let $w, w_0 \in W$ be arbitrary, and note that by induction hypothesis we have $w_2 \circ w \in W_{[n-1]}$. This means that there exists $w' \in W$ such that $w' \stackrel{n}{\cong} w_2 \circ w$ holds in $\frac{1}{2} \cdot X$, hence

$$\begin{aligned} \iota^{-1}(w'_1 \circ w_2)(w) &= \iota^{-1}(w'_1)(w_2 \circ w) * \iota^{-1}(w_2)(w) && \text{by definition of } \circ \\ &= \iota^{-1}(w'_1)(w') * \iota^{-1}(w_2)(w) && \text{by } w' \stackrel{n}{\cong} w_2 \circ w \\ &\subseteq \iota^{-1}(w'_1)(w' \circ w_0) * \iota^{-1}(w_2)(w \circ w_0) && \text{by hereditariness} \\ &= \iota^{-1}(w'_1)((w_2 \circ w) \circ w_0) * \iota^{-1}(w_2)(w \circ w_0) && \text{by } w' \stackrel{n}{\cong} w_2 \circ w \\ &= \iota^{-1}(w'_1 \circ w_2)(w \circ w_0) && \text{by definition of } \circ. \end{aligned}$$

Since w, w_0 were chosen arbitrarily, this calculation establishes $w'_1 \circ w_2 \in W$. \square

4 Step-indexed Possible World Semantics of Capabilities

We define semantic domains for the capabilities and types of the calculus described in Section 2,

$$\begin{aligned} Cap &= \frac{1}{2} \cdot W \rightarrow_{mon} UPred(Heap) \\ VT &= \frac{1}{2} \cdot W \rightarrow_{mon} UPred(Val) \\ MT &= \frac{1}{2} \cdot W \rightarrow_{mon} UPred(Val \times Heap) , \end{aligned}$$

so that $p \in Cap$ if and only if $\iota(p) \in W$. Next, we define operations on the semantic domains that correspond to the syntactic type and capability constructors. The most interesting of these is the one for arrow types. Given $T_1, T_2 \in 1/2 \cdot X \rightarrow UPred(Val \times Heap)$, $T_1 \rightarrow T_2$ in $\frac{1}{2} \cdot X \rightarrow UPred(Val)$ is defined on $x \in X$ as

$$\begin{aligned} \{(k, \text{fun } f(y)=t) \mid \forall j < k. \forall w \in W. \forall r \in UPred(Heap). \\ \forall(j, (v, h)) \in T_1(x \circ w) * \iota^{-1}(x \circ w)(emp) * r. \\ (j, (t[f:=\text{fun } f(y)=t, y:=v], h)) \in \mathcal{E}(T_2 * r)(x \circ w)\} , \end{aligned} \quad (4)$$

where $\mathcal{E}(T)$ is the extension of a world-indexed, uniform predicate on $Val \times Heap$ to one on $Exp \times Heap$. It is here where the index is linked to the operational semantics: $(k, (t, h)) \in \mathcal{E}(T)(x)$ if and only if for all $j \leq k, t', h'$,

$$\begin{aligned} (t \mid h) \mapsto^j (t' \mid h') \wedge (t' \mid h') \text{ irreducible} \\ \Rightarrow (k-j, (t', h')) \in \bigcup_{w' \in W} T(x \circ w') * \iota^{-1}(x \circ w')(emp) . \end{aligned}$$

Definition (4) realizes the key ideas of our model as follows. First, the universal quantification over $w \in W$ and subsequent use of the world $x \circ w$ builds in monotonicity, and intuitively means that $T_1 \rightarrow T_2$ is parametric in (and hence preserves) invariants that have been added by the procedure's context. In particular, (4) states that procedure application preserves this invariant, when viewed as the predicate $\iota^{-1}(x \circ w)(emp)$. By also conjoining r as an invariant we “bake in” the first-order frame property, which results in a subtyping axiom $T_1 \rightarrow T_2 \leq T_1 * C \rightarrow T_2 * C$ in the type system. The existential quantification over w' , in the definition of \mathcal{E} , allows us to “absorb” a part of the local heap description into the world. Finally, the quantification over indices $j < k$ in (4) achieves that $(T_1 \rightarrow T_2)(x)$ is uniform. There are three reasons why we require that j be *strictly* less than k . Technically, the use of $\iota^{-1}(x \circ w)$ in the definition “undoes” the scaling by $1/2$, and $j < k$ is needed to ensure the non-expansiveness of $T_1 \rightarrow T_2$ as a function $1/2 \cdot X \rightarrow UPred(Val)$. Moreover, it lets us prove the typing rule for *recursive* functions by induction on k . Finally, it means that \rightarrow is a contractive type constructor, which justifies the formal contractiveness assumption about arrow types that we made earlier. Intuitively, the use of $j < k$ for the arguments suffices since application consumes a step.

The function type constructor, as well as all the other type and capability constructors, restrict to Cap , VT and MT , respectively. With their help it becomes straightforward to define the interpretation of capabilities and types, and

to verify that the type equivalences hold with respect to this interpretation. We state this for the case of arrow types:

Lemma 5. *Let T_1, T_2 non-expansive functions from $\frac{1}{2} \cdot X$ to $UPred(\text{Val} \times \text{Heap})$.*

1. $T_1 \rightarrow T_2$ is non-expansive, and $(T_1 \rightarrow T_2)(x)$ is uniform for all $x \in X$.
2. $T_1 \rightarrow T_2 \in VT$.
3. The assignment of $T_1 \rightarrow T_2$ to T_1, T_2 is contractive.
4. Let $c \in \text{Cap}$ and $w \stackrel{\text{def}}{=} \iota(c)$. Then $(T_1 \rightarrow T_2) \otimes w = (T_1 \otimes w * c) \rightarrow (T_2 \otimes w * c)$.

Recall that there are two kinds of typing judgments, one for typing of values and the other for the typing of expressions. The semantics of a value judgement simply establishes truth with respect to all worlds w , environments η , and $k \in \mathbb{N}$:

$$\models (\Delta \vdash v : \tau) \stackrel{\text{def}}{\iff} \forall \eta. \forall w \in W. \forall k \in \mathbb{N}. \forall (k, \rho) \in \llbracket \Delta \rrbracket_\eta w. (k, \rho(v)) \in \llbracket \tau \rrbracket_\eta w .$$

Here $\rho(v)$ means the application of the substitution ρ to v . The judgement for expressions mirrors the interpretation of the arrow case for value types, in that there is also a quantification over heap predicates $r \in UPred(\text{Heap})$ and an existential quantification over $w' \in W$ through the use of \mathcal{E} :

$$\begin{aligned} \models (\Gamma \Vdash t : \chi) &\stackrel{\text{def}}{\iff} \forall \eta. \forall w \in W. \forall k \in \mathbb{N}. \forall r \in UPred(\text{Heap}). \\ &\forall (k, (\rho, h)) \in \llbracket \Gamma \rrbracket_\eta w * \iota^{-1}(w)(\text{emp}) * r. (k, (\rho(t), h)) \in \mathcal{E}(\llbracket \chi \rrbracket_\eta * r)(w). \end{aligned}$$

Theorem 6 (Soundness). *If $\Delta \vdash v : \tau$ then $\models (\Delta \vdash v : \tau)$, and if $\Gamma \Vdash t : \chi$ then $\models (\Gamma \Vdash t : \chi)$.*

To prove the theorem, we show that each typing rule preserves the truth of judgements. Detailed proofs for the shallow and deep frame rules are included in the appendix. Here, we consider the anti-frame rule. Its proof employs so-called commutative pairs [13, 17], a property expressed by the following lemma.

Lemma 7. *For all worlds $w_0, w_1 \in W$, there exist $w'_0, w'_1 \in W$ such that*

$$w'_0 = \iota(\iota^{-1}(w_0) \otimes w'_1), \quad w'_1 = \iota(\iota^{-1}(w_1) \otimes w'_0), \quad \text{and} \quad w_0 \circ w'_1 = w_1 \circ w'_0 .$$

Proof. The proof is along the lines of [17, Sect. 4]. Specifically, w'_0, w'_1 are obtained as fixed point of a contractive function F on $X \times X$, sending (x, x') to $(\iota(\iota^{-1}(w_0) \otimes x'), \iota(\iota^{-1}(w_1) \otimes x))$. In addition, since W is a non-empty and closed subset of X and \circ restricts to W by Lemma 4, this fixed point is in W . \square

Lemma 8 (Soundness of the anti-frame rule). *Suppose $\models (\Gamma \otimes C \Vdash t : \chi \otimes C * C)$. Then $\models (\Gamma \Vdash t : \chi)$.*

Proof. We prove $\models (\Gamma \Vdash t : \chi)$. Let $w \in W$, $k \in \mathbb{N}$, $r \in UPred(\text{Heap})$ and

$$(k, (\rho, h)) \in \llbracket \Gamma \rrbracket (w) * \iota^{-1}(w)(\text{emp}) * r .$$

We must prove $(k, (\rho(t), h)) \in \mathcal{E}(\llbracket \chi \rrbracket * r)(w)$. By Lemma 7,

$$w_1 = \iota(\iota^{-1}(w) \otimes w_2), \quad w_2 = \iota(\llbracket C \rrbracket \otimes w_1) \quad \text{and} \quad \iota(\llbracket C \rrbracket) \circ w_1 = w \circ w_2 \quad (5)$$

holds for some worlds w_1, w_2 in W .

First, we find a superset of the precondition $\llbracket \Gamma \rrbracket (w) * \iota^{-1}(w)(emp) * r$ in the assumption above, replacing the first two $*$ -conjunctions as follows:

$$\begin{aligned}
\llbracket \Gamma \rrbracket (w) &\subseteq \llbracket \Gamma \rrbracket (w \circ w_2) && \text{by monotonicity of } \llbracket \Gamma \rrbracket \text{ and } w_2 \in W \\
&= \llbracket \Gamma \rrbracket (\iota(\llbracket C \rrbracket) \circ w_1) && \text{since } \iota(\llbracket C \rrbracket) \circ w_1 = w \circ w_2 \\
&= \llbracket \Gamma \otimes C \rrbracket (w_1) && \text{by definition of } \otimes. \\
\iota^{-1}(w)(emp) &\subseteq \iota^{-1}(w)(emp \circ w_2) && \text{by monotonicity of } \iota^{-1}(w) \text{ and } w_2 \in W \\
&= \iota^{-1}(w)(w_2 \circ emp) && \text{since } emp \text{ is the unit} \\
&= (\iota^{-1}(w) \otimes w_2)(emp) && \text{by definition of } \otimes \\
&= \iota^{-1}(w_1)(emp) && \text{since } w_1 = \iota(\iota^{-1}(w) \otimes w_2).
\end{aligned}$$

Thus, by the monotonicity of separating conjunction, we have that

$$(k, (\rho, h)) \in \llbracket \Gamma \rrbracket (w) * \iota^{-1}(w)(emp) * r \subseteq \llbracket \Gamma \otimes C \rrbracket (w_1) * \iota^{-1}(w_1)(emp) * r. \quad (6)$$

By the assumed validity of the judgement $\Gamma \otimes C \Vdash t : \chi \otimes C * C$, (6) entails

$$(k, (\rho(t), h)) \in \mathcal{E}(\llbracket \chi \otimes C * C \rrbracket * r)(w_1). \quad (7)$$

We need to show that $(k, (\rho(t), h)) \in \mathcal{E}(\llbracket \chi \rrbracket * r)(w)$, so assume $(\rho(t) \mid h) \mapsto^j (t' \mid h')$ for some $j \leq k$ such that $(t' \mid h')$ is irreducible. From (7) we then obtain

$$(k-j, (t', h')) \in \bigcup_{w'} \llbracket \chi \otimes C * C \rrbracket (w_1 \circ w') * \iota^{-1}(w_1 \circ w')(emp) * r. \quad (8)$$

Now observe that we have

$$\begin{aligned}
&\llbracket \chi \otimes C * C \rrbracket (w_1 \circ w') * \iota^{-1}(w_1 \circ w')(emp) \\
&= \llbracket \chi \rrbracket (\iota(\llbracket C \rrbracket) \circ w_1 \circ w') * \llbracket C \rrbracket (w_1 \circ w') * \iota^{-1}(w_1 \circ w')(emp) \\
&= \llbracket \chi \rrbracket (\iota(\llbracket C \rrbracket) \circ w_1 \circ w') * \iota^{-1}(\iota(\llbracket C \rrbracket) \circ w_1 \circ w')(emp) \\
&= \llbracket \chi \rrbracket (w \circ w'') * \iota^{-1}(w \circ w'')(emp)
\end{aligned}$$

for $w'' \stackrel{def}{=} w_2 \circ w'$, since $w \circ w_2 = \iota(\llbracket C \rrbracket) \circ w_1$. Thus, (8) entails that $(k-j, (t', h'))$ is in $\bigcup_{w''} \llbracket \chi \rrbracket (w \circ w'') * \iota^{-1}(w \circ w'')(emp) * r$, and we are done. \square

5 Generalized Frame and Anti-frame Rules

The frame and anti-frame rules allow for hiding of *invariants*. However, to hide uses of local state, say for a function, it is, in general, not enough only to allow hiding of global invariants that are preserved across arbitrary sequences of calls and returns. For instance, consider the function f with local reference cell r :

$$\text{let } r = \text{ref } 0 \text{ in fun } f(g)=(inc(r);g();dec(r)) \quad (9)$$

If we write $\text{int } n$ for the singleton integer type containing n , we may wish to hide the capability $I = \{\sigma : \text{ref } (\text{int } 0)\}$ to capture the intuition that the cell $r : [\sigma]$

stores 0 upon termination. However, there could well be re-entrant calls to f and $\{\sigma : \text{ref}(\text{int } 0)\}$ is not an invariant for those calls.

Thus Pottier [14] proposed two extensions to the anti-frame rule that allows for hiding of families of invariants. The first idea is that each invariant in the family is a *local* invariant that holds for one level of the recursive call of a function. This extension allows us to hide “well-bracketed” [10] uses of local state. For instance, the \mathbb{N} -indexed family of invariants $I n = \{\sigma : \text{ref}(\text{int } n)\}$ can be used for (9); see the examples in [14]. The second idea is to allow each local invariant to *evolve* in some monotonic fashion; this allows us to hide even more uses of local state. The idea is related to the notion of evolving invariants for local state in recent work on reasoning about contextual equivalence [1, 10]. (Space limitations preclude us from including examples; please see [14] for examples.)

In summary, we want to allow the hiding of a family of capabilities $(I i)_{i \in \kappa}$ indexed over a preordered set (κ, \leq) . The preorder is used to capture that the local invariants can evolve in a monotonic fashion, as expressed in the new definition of the action of \otimes on function types (note that I on the right-hand side of \otimes now has kind $\kappa \rightarrow \text{CAP}$):

$$(\chi_1 \rightarrow \chi_2) \otimes I = \forall i. ((\chi_1 \otimes I) * I i \rightarrow \exists j \geq i. ((\chi_2 \otimes I) * I j))$$

Observe how this definition captures the intuitive idea: if the invariant $I i$ holds when the function is called then, upon return, we know that an invariant $I j$ (for $j \in \kappa, j \geq i$) holds. Different recursive calls may use different local invariants due to the quantification over i . The generalized frame and anti-frame rules are:

$$[GF] \frac{\Gamma \Vdash t : \chi}{\Gamma \otimes I * I i \Vdash t : \exists j \geq i. (\chi \otimes I) * I j} \quad [GAF] \frac{\Gamma \otimes I \Vdash t : \exists i. (\chi \otimes I) * I i}{\Gamma \Vdash t : \chi}$$

We now show how to extend our model of the type and capability calculus to accommodate hiding of such more expressive families of invariants. Naturally, the first step is to refine our notion of world, since the worlds are used to describe hidden invariants.

Generalized worlds and generalized world extension. Suppose \mathcal{K} is a (small) collection of preordered sets. We write \mathcal{K}^* for the finite sequences over \mathcal{K} , ε for the empty sequence, and use juxtaposition to denote concatenation. For convenience, we will sometimes identify a sequence $\alpha = \kappa_1, \dots, \kappa_n$ over \mathcal{K} with the preorder $\kappa_1 \times \dots \times \kappa_n$. As in Section 3, we define the worlds for the Kripke model in two steps, starting from an equation without any monotonicity requirements: $CBUlt_{ne}$ has all non-empty coproducts, and there is a unique solution to the two equations

$$X \cong \sum_{\alpha \in \mathcal{K}^*} X_\alpha, \quad X_{\kappa_1, \dots, \kappa_n} = (\kappa_1 \times \dots \times \kappa_n) \rightarrow (\frac{1}{2} \cdot X \rightarrow UPred(\text{Heap})), \quad (10)$$

with isomorphism $\iota : \sum_{\alpha \in \mathcal{K}^*} X_\alpha \rightarrow X$ in $CBUlt_{ne}$, where each $\kappa \in \mathcal{K}$ is equipped with the discrete metric. Each X_α consists of the α -indexed families of (world-dependent) predicates so that, in comparison to Section 3, X consists of all these families rather than individual predicates.

The composition operation $\circ : X \times X \rightarrow X$ is now given by $x_1 \circ x_2 = \iota(\langle \alpha_1 \alpha_2, p \rangle)$ where $\langle \alpha_i, p_i \rangle = \iota^{-1}(x_i)$, and where $p \in X_{\alpha_1 \alpha_2}$ is defined by

$$p(i_1 i_2)(x) = p_1(i_1)(x_2 \circ x) * p_2(i_2)(x) .$$

for $i_1 \in \alpha_1, i_2 \in \alpha_2$. That is, the combination of an α_1 -indexed family p_1 and an α_2 -indexed family p_2 is a family p over $\alpha_1 \alpha_2$, but there is no interaction between the index components i_1 and i_2 : they concern disjoint regions of the heap.

From here on we can proceed essentially as in Section 3: The composition operation can be shown associative, with a left and right unit given by $emp = \iota(\langle \varepsilon, \lambda_-, \dots I \rangle)$. For $f : \frac{1}{2} \cdot X \rightarrow Y$ the extension operation $(f \otimes x)(x') = f(x \circ x')$ is also defined as before (but with respect to the solution (10) and the new \circ operation). We then carve out from X the subset of hereditarily monotonic functions W , which we again obtain as fixed point of a contractive function on the closed and non-empty subsets of X . Let us write \sim for the (recursive) partial equivalence relation on X where $\iota(\langle \alpha_1 \alpha_2, p \rangle) \sim \iota(\langle \alpha_2 \alpha_1, q \rangle)$ holds if $p(i_1 i_2)(x_1) = q(i_2 i_1)(x_2)$ for all $i_1 \in \alpha_1, i_2 \in \alpha_2$ and $x_1 \sim x_2$. Then $w \in W$ iff $w \sim w$ and

$$\exists \alpha, p. w = \iota(\langle \alpha, p \rangle) \wedge \forall i \in \alpha. \forall w_1, w_2 \in W. p(i)(w_1) \subseteq p(i)(w_1 \circ w_2) .$$

Finally, the proof of Lemma 4 can be adapted to show that the operation \circ restricts to the subset W .

Semantics of capabilities and types. The definition of function types changes as follows: given $x \in X$, $(k, \text{fun } f(y)=t) \in (T_1 \rightarrow T_2)(x)$ if and only if

$$\begin{aligned} & \forall j < k. \forall w \in W \text{ where } \iota^{-1}(x \circ w) = \langle \alpha, p \rangle. \forall r \in UPred(Heap). \forall i \in \alpha. \\ & \forall (j, (v, h)) \in T_1(x \circ w) * p(i)(emp) * r. \\ & (j, t[f:=\text{fun } f(y)=t, y:=v], h) \in \mathcal{E}(T_2 * r, x \circ w, i) , \end{aligned}$$

where the extension to expressions now depends on $i \in \alpha$: $(k, t) \in \mathcal{E}(T, x, i)$ if

$$\begin{aligned} & \forall j \leq k, t', h'. (t | h) \mapsto^j (t' | h') \wedge (t' | h') \text{ irreducible} \\ & \Rightarrow (k - j, (t', h')) \in \bigcup_{w \in W, i_1 \in \alpha, i_2 \in \beta, i_1 \geq i} T(x \circ w) * q(i_1 i_2)(emp) \end{aligned}$$

for $\langle \alpha \beta, q \rangle = \iota^{-1}(x \circ w)$.

Next, one proves the analogue of Lemma 5 which shows the well-definedness of $T_1 \rightarrow T_2$ and (a semantic variant of) the distribution axiom for generalized invariants: in particular, given $p \in \kappa \rightarrow Cap$ and setting $w \stackrel{\text{def}}{=} \iota(\langle \kappa, p \rangle)$,

$$(T_1 \rightarrow T_2) \otimes w = \forall_{i \in \kappa} ((T_1 \otimes w) * p i) \rightarrow \exists_{j \geq i} ((T_2 \otimes w) * p j)$$

where \forall and \exists denote the pointwise intersection and union of world-indexed uniform predicates.

Once similar properties are proved for the other type and capability constructors (which do not change for the generalized invariants), we obtain:

Theorem 9 (Soundness). *The generalized frame and anti-frame rules [GF] and [GAF] are sound.*

In particular, this theorem shows that all the reasoning about the use of local state in the (non-trivial) examples considered by Pottier in [14] is sound.

6 Conclusion and Future Work

We have developed the first soundness proof of the anti-frame rule in the expressive type and capability system of Charguéraud and Pottier by constructing a Kripke model of the system. For our model, we have used a new approach to the construction of worlds by defining them as a recursive subset of a recursively defined metric space, thus avoiding a tedious explicit inverse-limit construction. We have shown that this approach scales, by also extending the model to show soundness of Pottier’s generalized frame and anti-frame rules. Future work includes exploring some of the orthogonal extensions of the basic type and capability system: group regions [8] and fates & predictions [11].

Acknowledgments. We would like to thank François Pottier for many interesting discussions about frame and anti-frame rules.

A Definitions

In this section we give the details of the programming language and the type and capability system. For more details and motivation we refer to [8, 13, 6, 17].

Figures 2 and 3 give the syntax and operational semantics of a standard call-by-value higher-order language with recursive procedures. Figures 4 and 5 give the syntax and a structural equivalence relation on types, and Figure 6 presents some subtyping axioms. Figure 7 gives the typing rules that define the typing judgements for values and expressions.

$$\begin{aligned}
 v &::= x \mid () \mid \text{inj}^i v \mid (v_1, v_2) \mid \text{fun } f(x)=t \mid l \\
 t &::= v \mid (vt) \mid \text{case}(v_1, v_2, v) \mid \text{proj}^i v \mid \text{ref } v \mid \text{get } v \mid \text{set } v
 \end{aligned}$$

Fig. 2. Syntax of values and expressions

$$\begin{aligned}
 (\text{fun } f(x)=t) v \mid h &\mapsto t[f := \text{fun } f(x)=t, x := v] \mid h \\
 \text{proj}^i(v_1, v_2) \mid h &\mapsto v_i \mid h && \text{for } i = 1, 2 \\
 \text{case}(v_1, v_2, \text{inj}^i v) \mid h &\mapsto v_i v \mid h && \text{for } i = 1, 2 \\
 \text{ref } v \mid h &\mapsto l \mid h \cdot [l \mapsto v] && \text{if } l \notin \text{dom}(h) \\
 \text{get } l \mid h &\mapsto h(l) \mid h && \text{if } l \in \text{dom}(h) \\
 \text{set } (l, v) \mid h &\mapsto () \mid h[l := v] && \text{if } l \in \text{dom}(h) \\
 vt \mid h &\mapsto vt' \mid h' && \text{if } t \mid h \mapsto t' \mid h'

B Proofs

This section gives details for the metric on relations, and how this is used to carve out the hereditarily monotonic worlds. Moreover, we give the interpretation of capabilities and types with respect to these hereditarily monotonic worlds.

B.1 Relations on complete ultrametric spaces

Let $(X, d) \in \text{CBUlt}_{ne}$, and let $\mathcal{R}(X)$ be the collection of all non-empty and closed relations $R \subseteq X$.

Variables	$\xi ::= \alpha \mid \beta \mid \gamma \mid \sigma$
Capabilities	$C ::= C \otimes C \mid \emptyset \mid C * C \mid \{\sigma : \theta\} \mid \exists \sigma. C \mid \gamma \mid \mu \gamma. C \mid \forall \xi. C$
Value types	$\tau ::= \tau \otimes C \mid 0 \mid 1 \mid \text{int} \mid \tau + \tau \mid \tau \times \tau \mid \chi \rightarrow \chi \mid [\sigma] \mid \alpha \mid \mu \alpha. \tau \mid \forall \xi. \tau$
Memory types	$\theta ::= \theta \otimes C \mid \tau \mid \theta + \theta \mid \theta \times \theta \mid \text{ref } \theta \mid \theta * C \mid \exists \sigma. \theta \mid \beta \mid \mu \beta. \theta \mid \forall \xi. \theta$
Computation types	$\chi ::= \chi \otimes C \mid \tau \mid \chi * C \mid \exists \sigma. \chi$
Value contexts	$\Delta ::= \Delta \otimes C \mid \emptyset \mid \Delta, x : \tau$
Linear contexts	$\Gamma ::= \Gamma \otimes C \mid \emptyset \mid \Gamma, x : \chi \mid \Gamma * C$

Fig. 4. Capabilities and types

Proposition 10. *Let $d : \mathcal{R}(X) \times \mathcal{R}(X) \rightarrow \mathbb{R}$ be defined by*

$$d(R, S) = \inf \{2^{-n} \mid R_{[n]} = S_{[n]}\} .$$

Then $(\mathcal{R}(X), d)$ is a complete, 1-bounded, non-empty ultrametric space.

Proof. First, $\mathcal{R}(X)$ is non-empty since it contains X itself, and d is well-defined since $R_{[0]} = S_{[0]}$ holds for any $R, S \in \mathcal{R}$. Next, since $R = S$ is equivalent to $R_{[n]} = S_{[n]}$ for all $n \in \mathbb{N}$, it follows that $d(R, S) = 0$ if and only if $R = S$. That the ultrametric inequality $d(R, S) \leq \max\{d(R, T), d(T, S)\}$ holds is immediate by the definition of d , as is the fact that d is symmetric and 1-bounded.

To show completeness, assume that $(R_n)_{n \in \mathbb{N}}$ is a Cauchy sequence in $\mathcal{R}(X)$. Without loss of generality we may assume that $d(R_n, R_{n+1}) \leq 2^{-n}$ holds for all $n \in \mathbb{N}$, and therefore that $(R_n)_{[n]} = (R_{n+1})_{[n]}$ for all $n \geq 0$. Writing S_n for $(R_n)_{[n]}$, we define $R \subseteq X$ by

$$R \stackrel{\text{def}}{=} \bigcap_{n \geq 0} S_n .$$

R is closed since each S_n is closed. We now prove that R is non-empty, and therefore $R \in \mathcal{R}(X)$, by inductively constructing a sequence $(x_n)_{n \in \mathbb{N}}$ with $x_n \in S_n$: Let x_0 be an arbitrary element in $S_0 = X$. Having chosen x_0, \dots, x_n , we pick some $x_{n+1} \in S_{n+1}$ such that $x_{n+1} \stackrel{n}{=} x_n$; this is always possible because $S_n = (S_{n+1})_{[n]}$ by our assumption on the sequence $(R_n)_{n \in \mathbb{N}}$. Clearly this is a Cauchy sequence in X , and from $S_n \supseteq S_{n+1}$ it follows that $(x_n)_{n \geq k}$ is in fact a sequence in S_k for each $k \in \mathbb{N}$. But then also $\lim_{n \in \mathbb{N}} x_n$ is in S_k for each k , and thus also in R .

We now prove that R is the limit of the sequence $(R_n)_{n \in \mathbb{N}}$. By definition of d it suffices to show that $R_{[k]} = (R_k)_{[k]}$ for all $k \geq 1$, or equivalently, that $R_{[k]} = S_k$. From the definition of R , $R \subseteq S_k$, which immediately entails $R_{[k]} \subseteq (S_k)_{[k]} = S_k$.

To prove the other direction, i.e., $S_k \subseteq R_{[k]}$, assume that $x \in S_k$. To show that $x \in R_{[k]}$ we inductively construct a Cauchy sequence $(x_n)_{n \geq k}$ with $x_n \in S_n$,

monoids

Fig. 7. Typing of values and expressions

$x_k = x$ and $x_{n+1} \stackrel{n}{=} x_n$ analogously to the one above. Then $\lim_m x_m$ is in S_n for each $n \geq 0$, and thus also in R . Since $d_X(x_k, \lim_{n \geq k} x_n) \leq 2^{-k}$ by the ultrametric inequality, $x_k \in R_{[k]}$, or equivalently, $x \in R_{[k]}$. \square

B.2 Hereditarily monotonic recursive worlds

Let the function $\Phi : \mathcal{P}(X) \rightarrow \mathcal{P}(X)$ be defined by $\Phi(A) = \{\iota(p) \mid \forall x, x_0 \in A. p(x) \subseteq p(x \circ x_0)\}$.

Lemma 11. *For each $A \in \mathcal{R}$, $\Phi(A)$ is non-empty and closed.*

Proof. $\Phi(A)$ is non-empty since it contains the constant functions into $UPred(Heap)$. As in [7], one can use the completeness of $UPred(Heap)$ and the way its metric interacts with subset inclusion to show that $\Phi(A)$ is closed. \square

Lemma 12. *Φ is contractive: $A \stackrel{n}{=} B$ implies $\Phi(A) \stackrel{n+1}{=} \Phi(B)$.*

Proof. Let $n \geq 0$ and assume $A \stackrel{n}{=} B$. Let $\iota(p) \in \Phi(A)_{[n+1]}$. We must show that $\iota(p) \in \Phi(B)_{[n+1]}$. By definition there exists $\iota(q) \in \Phi(A)$ such that $p \stackrel{n+1}{=} q$. Set $r(w) = q(w)_{[n+1]}$. Then $r \stackrel{n+1}{=} p$ and it suffices to show that $\iota(r) \in \Phi(B)$. To this end, let $w_0, w_1 \in B$. By assumption there exist $w'_0, w'_1 \in A$ such that $w'_0 \stackrel{n}{=} w_0$ and $w'_1 \stackrel{n}{=} w_1$ in X , or equivalently, $w'_0 \stackrel{n+1}{=} w_0$ and $w'_1 \stackrel{n+1}{=} w_1$ in $\frac{1}{2} \cdot X$. Using the non-expansiveness of \circ , this also implies $w'_0 \circ w'_1 \stackrel{n+1}{=} w_0 \circ w_1$ in $\frac{1}{2} \cdot X$. Since $q(w_0) \stackrel{n+1}{=} q(w'_0) \subseteq q(w'_0 \circ w'_1) \stackrel{n+1}{=} q(w_0 \circ w_1)$ by the non-expansiveness of q and the assumption that $\iota(q) \in \Phi(A)$ we obtain the required inclusion $r(w_0) \subseteq r(w_0 \circ w_1)$. \square

Lemma 13. *For any preorder (A, \sqsubseteq) , $\frac{1}{2} \cdot W \rightarrow_{mon} UPred(A)$ is a non-empty and closed subset of $\frac{1}{2} \cdot X \rightarrow UPred(A)$.*

Proof. Similar to the proof of Lemma 11. \square

B.3 Closure of W under composition

Lemma 14. *For all $n \in \mathbb{N}$, if $w_1, w_2 \in W$ then $w_1 \circ w_2 \in W_{[n]}$.*

Since $W = \bigcap_n W_{[n]}$ it follows that $w_1, w_2 \in W \Rightarrow w_1 \circ w_2 \in W$.

Proof. Since $W_{[0]} = X$ the claim trivially holds in case $n = 0$. Now suppose $n > 0$ and let $w_1, w_2 \in W$; we must prove that $w_1 \circ w_2 \in W_{[n]}$. Let w'_1 be such that $\iota^{-1}(w'_1)(w) = \iota^{-1}(w_1)(w)_{[n]}$. Observe that $w'_1 \in W$, and $w \stackrel{n}{=} w'$ in $\frac{1}{2} \cdot X$ implies $w'_1(w) = w'_1(w')$. Since $w_1 \stackrel{n}{=} w'_1$, the non-expansiveness of \circ implies $w_1 \circ w_2 \stackrel{n}{=} w'_1 \circ w_2$, and thus it suffices to show that $w'_1 \circ w_2 \in W = \Phi(W)$. To

see this, let $w, w_0 \in W$. Note that by induction hypothesis $w_2 \circ w \in W_{[n-1]}$, i.e., there exists $w' \in W$ such that $w' \stackrel{n}{=} w_2 \circ w$ holds in $\frac{1}{2} \cdot W$. We thus obtain

$$\begin{aligned}
\iota^{-1}(w'_1 \circ w_2)(w) &= \iota^{-1}(w'_1)(w_2 \circ w) * \iota^{-1}(w_2)(w) \\
&= \iota^{-1}(w'_1)(w') * \iota^{-1}(w_2)(w) \\
&\subseteq \iota^{-1}(w'_1)(w' \circ w_0) * \iota^{-1}(w_2)(w \circ w_0) \\
&= \iota^{-1}(w'_1)((w_2 \circ w) \circ w_0) * \iota^{-1}(w_2)(w \circ w_0) \\
&= \iota^{-1}(w'_1 \circ w_2)(w \circ w_0) ,
\end{aligned}$$

i.e., $w'_1 \circ w_2 \in W$. □

B.4 Closure under extension

Lemma 15. *If $w \in W$ and $f \in \frac{1}{2} \cdot W \rightarrow_{\text{mon}} \text{UPred}(A)$ then $f \otimes w \in \frac{1}{2} \cdot W \rightarrow_{\text{mon}} \text{UPred}(A)$. Moreover, the assignment of $f \otimes w$ to f and w is non-expansive as a function of f and contractive as a function of w .*

Proof. Let $w_1, w_2 \in W$. Then $w \circ w_1 \in W$ by Lemma 14, and hence

$$(f \otimes w)(w_1) = f(w \circ w_1) \subseteq f((w \circ w_1) \circ w_2) = (f \otimes w)(w_1 \circ w_2)$$

by the assumption that f is in $\frac{1}{2} \cdot W \rightarrow_{\text{mon}} \text{UPred}(A)$. □

B.5 Closure under universal quantification

Let S be a set (discrete metric space), and suppose $F : S \rightarrow (\frac{1}{2} \cdot X \rightarrow \text{UPred}(A))$. Then we define $\forall F : \frac{1}{2} \cdot X \rightarrow \text{UPred}(A)$ by

$$(\forall F)(x) = \bigcap_{s \in S} F(s)(x)$$

Lemma 16. *With F as above, $\forall F$ is non-expansive, and $(\forall F)(x)$ is upwards closed and uniform. If $F(s) \in \frac{1}{2} \cdot W \rightarrow_{\text{mon}} \text{UPred}(A)$ for all $s \in S$ then $\forall F \in \frac{1}{2} \cdot W \rightarrow_{\text{mon}} \text{UPred}(A)$. The assignment of $\forall F$ to F is non-expansive.*

This observation can be used to justify quantification over types, capabilities and region names in *Cap*, *VT* and *MT*.

B.6 Recursion

Cap, *VT* and *MT* are non-empty and closed subsets of complete ultrametric spaces, by Lemma 13. Thus, any contractive function that restricts to these sets has a unique fixed point in the respective set. This observation can be used to justify recursive definitions of capabilities and types, noting that formal contractiveness of a syntactic type expression ensures contractiveness of its interpretation (see below). Moreover, the assignment to a contractive function of its unique fixed point is a non-expansive operation.

B.7 Closure of Cap under separating conjunction

Lemma 17. *If $f, g \in Cap$ then $f * g \in Cap$. Moreover, the assignment of $f * g$ to f, g is non-expansive.*

Proof. Let $w_1, w_2 \in W$, then $(f * g)(w_1) = f(w_1) * g(w_1) \subseteq f(w_1 \circ w_2) * g(w_1 \circ w_2) = (f * g)(w_1 \circ w_2)$ follows from $f, g \in Cap$ and the monotonicity of separating conjunction on $UPred(Heap)$. \square

B.8 Closure of Cap under singleton capabilities

For $v \in Val$ and f in $\frac{1}{2} \cdot X \rightarrow UPred(Heap)$ define $\{v : f\}$ in $\frac{1}{2} \cdot X \rightarrow UPred(Heap)$ by

$$\{v : f\}(x) \stackrel{def}{=} \{(k, h) \mid (k, (v, h)) \in f(x)\}$$

Lemma 18. *With v, f as above, $\{v : f\}$ is non-expansive, and $\{v : f\}(x)$ is upwards closed and uniform for all $x \in X$. If $f \in Cap$ then $\{v : f\} \in Cap$, and the assignment of $\{v : f\}$ to f is non-expansive.*

Proof. The non-expansiveness of $\{v : f\}$ follows from the non-expansiveness of f . Similarly, the claim $\{v : f\}(x) \in UPred(Heap)$ follows from $f(x) \in UPred(Val \times Heap)$. Finally, if $w_1, w_2 \in W$ then $\{v : f\}(w_1) \subseteq \{v : f\}(w_1 \circ w_2)$ follows if $f \in Cap$, for then $f(w_1) \subseteq f(w_1 \circ w_2)$. \square

B.9 Closure of VT under sums

For f_1, f_2 in $\frac{1}{2} \cdot X \rightarrow UPred(Val)$ define $f_1 + f_2$ in $\frac{1}{2} \cdot X \rightarrow UPred(Val)$ by

$$(f_1 + f_2)(x) \stackrel{def}{=} \{(k, \text{inj}^i v) \mid k > 0 \Rightarrow (k-1, v) \in f_i(x)\}$$

Lemma 19. *With f_1, f_2 as above, $f_1 + f_2$ is non-expansive, and $(f_1 + f_2)(x)$ is uniform for all $x \in X$. If $f_1, f_2 \in VT$ then $f_1 + f_2 \in VT$, and the assignment of $f_1 + f_2$ to f_1, f_2 is contractive.*

Proof. Let $x \stackrel{n}{=} x'$ in $1/2 \cdot X$ and $f_1 \stackrel{n}{=} f'_1$ and $f_2 \stackrel{n}{=} f'_2$. Then, for any $0 < k \leq n$, $(k-1, v) \in f_i(x)$ iff $(k-1, v) \in f'_i(x')$ by the non-expansiveness of application and the definition of the metric on $UPred(Val)$. Thus $(f_1 + f_2)(x) \stackrel{n+1}{=} (f'_1 + f'_2)(x')$ from which the non-expansiveness of $f_1 + f_2$ as well as the contractiveness of the assignment of $f_1 + f_2$ to f_1, f_2 follows. That $(f_1 + f_2)(x) \in UPred(Val)$ follows from $f_i(x) \in UPred(Val)$. Finally, if $w_1, w_2 \in W$ then $(f_1 + f_2)(w_1) \subseteq (f_1 + f_2)(w_1 \circ w_2)$ follows from by definition of $f_1 + f_2$ if $f_1, f_2 \in VT$, since then $f_i(w_1) \subseteq f_i(w_1 \circ w_2)$ holds. \square

B.10 Closure of VT under products

For f_1, f_2 in $\frac{1}{2} \cdot X \rightarrow UPred(Val)$ define $f_1 \times f_2$ in $\frac{1}{2} \cdot X \rightarrow UPred(Val)$ by

$$(f_1 \times f_2)(x) \stackrel{def}{=} \{(k, (v_1, v_2)) \mid k > 0 \Rightarrow (k-1, v_i) \in f_i(x)\}$$

Lemma 20. *With f_1, f_2 as above, $f_1 \times f_2$ is non-expansive, and $(f_1 \times f_2)(x)$ is uniform for all $x \in X$. If $f_1, f_2 \in VT$ then $f_1 \times f_2 \in VT$, and the assignment of $f_1 \times f_2$ to f_1, f_2 is contractive.*

Proof. Similar to the previous proof. Let $x \stackrel{n}{\approx} x'$ in $1/2 \cdot X$ and $f_1 \stackrel{n}{\approx} f'_1$ and $f_2 \stackrel{n}{\approx} f'_2$. Then, for any $0 < k \leq n$, $(k-1, v) \in f_i(x)$ iff $(k-1, v) \in f'_i(x')$ by the non-expansiveness of function application and the definition of the metric on $UPred(Val)$. Thus $(f_1 \times f_2)(x) \stackrel{n+1}{\approx} (f_1 \times f_2)(x')$. That $(f_1 \times f_2)(x) \in UPred(Val)$ follows from $f_i(x) \in UPred(Val)$. Finally, if $w_1, w_2 \in W$ then the inclusion $(f_1 \times f_2)(w_1) \subseteq (f_1 \times f_2)(w_1 \circ w_2)$ follows by definition of \times if $f_1, f_2 \in VT$. \square

B.11 Extension to expressions

For $p \in UPred(A \times Heap)$ and $r \in UPred(Heap)$ we define $p * r$ by

$$p * r = \{(k, (a, h \cdot h')) \mid (k, (a, h)) \in p \wedge (k, h') \in r\}.$$

Then $p * r \in UPred(A \times Heap)$. This operation can be lifted pointwise, and if $f \in MT$ and $p \in Cap$ then $f * p \in MT$. Sometimes, we will view $r \in UPred(Heap)$ as the constant function $r \in Cap$, and thus write $f * r$ for this pointwise lifting.

Using the former operation on uniform predicates, we define the following extension of memory types from values to expressions.

Definition 21 (Expression typing). *Let p in $\frac{1}{2} \cdot X \rightarrow UPred(Val \times Heap)$. Then the function $\mathcal{E}(p) : X \rightarrow UPred(Exp \times Heap)$ is defined by $(k, (t, h)) \in \mathcal{E}(p)(x)$ iff*

$$\begin{aligned} \forall j \leq k, t', h'. (t \mid h) \mapsto^j (t' \mid h') \wedge (t' \mid h') \text{ irreducible} \\ \Rightarrow (k-j, (t', h')) \in \bigcup_{w \in W} p(x \circ w) * \iota^{-1}(x \circ w)(emp). \end{aligned}$$

Note that in this definition p is a contractive function on X whereas $\mathcal{E}(p)$ is merely non-expansive. The reason is that the conclusion uses the world x as a heap predicate, qua $\iota^{-1}(x \circ w)(emp)$, i.e. there is scaling involved, and j may in fact be 0.

Lemma 22. *With p as above, $\mathcal{E}(p)$ is non-expansive, and $\mathcal{E}(p)(x)$ is upwards closed and uniform for all $x \in X$. Moreover, the assignment of $\mathcal{E}(p)$ to p is non-expansive.*

Proof. Similar to the previous proofs. We observe that $p \stackrel{n}{\approx} p'$ and $x \stackrel{n}{\approx} x'$ in X implies $p(x \circ w) \stackrel{n}{\approx} p'(x' \circ w)$ and $\iota^{-1}(x \circ w)(emp) \stackrel{n}{\approx} \iota^{-1}(x' \circ w)(emp)$, and thus $\mathcal{E}(p)(x) \stackrel{n}{\approx} \mathcal{E}(p')(x')$. Thus, for $p = p'$ we obtain the non-expansiveness of $\mathcal{E}(p)$, and for $x = x'$ we obtain the non-expansiveness of the assignment of $\mathcal{E}(p)$ to p by the definition of the sup metric. \square

B.12 Closure of VT under arrows

For p, q in $\frac{1}{2} \cdot X \rightarrow UPred(Val \times Heap)$ define $p \rightarrow q$ in $\frac{1}{2} \cdot X \rightarrow UPred(Val)$ on $x \in X$ as

$$\begin{aligned} \{ & (k, \text{fun } f(y)=t) \mid \forall j < k. \forall w \in W. \forall r \in UPred(Heap). \\ & \forall (j, (v, h)) \in p(x \circ w) * \iota^{-1}(x \circ w)(\text{emp}) * r. \\ & (j, (t[f:=\text{fun } f(y)=t, y:=v], h)) \in \mathcal{E}(q * r)(x \circ w) \} \end{aligned}$$

Lemma 23. *With p, q as above, $p \rightarrow q$ is non-expansive, and $(p \rightarrow q)(x)$ is uniform for all $x \in X$. Moreover, $p \rightarrow q \in VT$, and the assignment of $p \rightarrow q$ to p, q is contractive.*

Proof. The non-expansiveness is straightforward to check, using Lemma 22. The uniformity is ensured by the explicit quantification over $j < k$ in the definition of $(p \rightarrow q)(x)$. Similarly, that $p \rightarrow q \in VT$ is guaranteed by the explicit quantification over $w \in W$ in the definition of $(p \rightarrow q)(x)$, using the closure of W under \circ (Lemma 14). Finally, the contractiveness of $\cdot \rightarrow \cdot$ follows since $p(x \circ w)$ and $\mathcal{E}(q)(x \circ w)$ are only considered up to index j which is strictly below k . \square

B.13 Inclusion of VT into MT

The inclusion of value types into memory types,

$$f \in (\frac{1}{2} \cdot X \rightarrow UPred(Val)) \mapsto \lambda x. \{ (k, (v, h)) \mid h \in Heap \wedge (k, v) \in f(x) \},$$

is non-expansive and maps into non-expansive functions from $\frac{1}{2} \cdot X$ to the space $UPred(Val \times Heap)$. If $f \in VT$ then the right hand side is in MT .

B.14 Closure of MT under sums

For f_1, f_2 in $\frac{1}{2} \cdot X \rightarrow UPred(Val \times Heap)$ define the function $f_1 + f_2$ in $\frac{1}{2} \cdot X \rightarrow UPred(Val \times Heap)$ by

$$(f_1 + f_2)(x) \stackrel{\text{def}}{=} \{ (k, (\text{inj}^i v, h)) \mid k > 0 \Rightarrow (k-1, (v, h)) \in f_i(x) \}.$$

As with the sum types on values, this is well-defined, in MT if both f_1 and f_2 are in MT , and the assignment of $f_1 + f_2$ to f_1 and f_2 is contractive.

B.15 Closure of MT under products

For f_1, f_2 in $\frac{1}{2} \cdot X \rightarrow UPred(Val \times Heap)$ we define the function $f_1 \times f_2$ in $\frac{1}{2} \cdot X \rightarrow UPred(Val \times Heap)$ by

$$(f_1 \times f_2)(x) \stackrel{\text{def}}{=} \{ (k, ((v_1, v_2), h_1 \cdot h_2)) \mid k > 0 \Rightarrow (k-1, (v_i, h_i)) \in f_i(x) \}.$$

As with the product types on values, this is well-defined, $f_1 \times f_2$ is in MT if both f_1 and f_2 are in MT , and the assignment of $f_1 \times f_2$ to f_1 and f_2 is contractive.

B.16 Closure of MT under reference types

For f in $\frac{1}{2} \cdot X \rightarrow UPred(Val \times Heap)$ define $ref(f)$ in $\frac{1}{2} \cdot X \rightarrow UPred(Val \times Heap)$ by

$$ref(f)(x) \stackrel{def}{=} \{(k, (l, h \cdot [l \mapsto v])) \mid k > 0 \Rightarrow (k-1, (v, h)) \in f(x)\} .$$

Lemma 24. *With f as above, $ref(f)$ is non-expansive, and $ref(f)(x)$ is upwards closed and uniform for all $x \in X$. If $f \in MT$ then $ref(f) \in MT$, and the assignment of $ref(f)$ to f is contractive.*

B.17 Interpretation of types and capabilities

The interpretation depends on an environment η , which maps region names $\sigma \in RegName$ to closed values $\eta(\sigma) \in Val$, capability variables γ to semantic capabilities $\eta(\gamma) \in Cap$, and type variables α and β to semantic types $\eta(\alpha) \in VT$ and $\eta(\beta) \in MT$. Then, we use the semantic type constructors in the evident way, for instance defining $\llbracket \{\sigma : \theta\} \rrbracket_\eta = \{\eta(\sigma) : \llbracket \theta \rrbracket_\eta\}$ and $\llbracket \chi_1 \rightarrow \chi_2 \rrbracket_\eta = \llbracket \chi_1 \rrbracket_\eta \rightarrow \llbracket \chi_2 \rrbracket_\eta$. Importantly, we have the extension operation available to interpret invariant extension:

$$\llbracket C_1 \otimes C_2 \rrbracket_\eta = \llbracket C_1 \rrbracket_\eta \otimes \iota(\llbracket C_2 \rrbracket_\eta) ,$$

and similarly for $\tau \otimes C$ and $\theta \otimes C$.

We end up with interpretations $\llbracket C \rrbracket_\eta \in Cap$, $\llbracket \tau \rrbracket_\eta \in VT$, and $\llbracket \theta \rrbracket_\eta \in MT$.

B.18 Distribution of \otimes over \rightarrow

As an example of validating the type equivalence in the model we prove, on the semantic level, that the distribution axiom for arrow types holds.

Lemma 25. *Let $f_1, f_2 \in MT$ and $p \in Cap$. Then $(f_1 \rightarrow f_2) \otimes p = (f_1 \otimes p * p) \rightarrow (f_2 \otimes p * p)$.*

Proof. Let $x \in X$ and $(k, (\text{fun } f(y)=t)) \in ((f_1 \rightarrow f_2) \otimes p)(x) = (f_1 \rightarrow f_2)(\iota(p) \circ x)$. We must prove that $(k, (\text{fun } f(y)=t)) \in (f_1 \otimes p * p) \rightarrow (f_2 \otimes p * p)$. To this end, let $j < k$, $w \in W$, $r \in UPred(Heap)$, and suppose

$$\begin{aligned} (j, (v, h)) &\in (f_1 \otimes p * p)(x \circ w) * \iota^{-1}(x \circ w)(emp) * r \\ &= f_1(\iota(p) \circ x \circ w) * p(x \circ w) * \iota^{-1}(x \circ w)(emp) * r \\ &= f_1(\iota(p) \circ x \circ w) * \iota^{-1}(\iota(p) \circ x \circ w)(emp) * r . \end{aligned}$$

Then, by assumption, $(j, (t[f:=\text{fun } f(y)=t, y:=v], h)) \in \mathcal{E}(f_2 * r)(\iota(p) \circ x \circ w)$. By unfolding the definition of \mathcal{E} , the latter is seen to be equivalent to

$$(j, (t[f:=\text{fun } f(y)=t, y:=v], h)) \in \mathcal{E}(f_2 \otimes p * p * r)(x \circ w) ,$$

and thus $(k, (\text{fun } f(y)=t)) \in (f_1 \otimes p * p) \rightarrow (f_2 \otimes p * p)$.

The other direction is similar. \square

Remark 26. Note that we did not use the fact that $f_1, f_2 \in MT$ and $p \in Cap$. This is in line with the semantics given in the earlier work by Birkedal et al. [6]. There, the anti-frame rule was not considered and a model based on the simpler set of worlds X sufficed; the language also contained all of the distribution axioms that we consider here.

B.19 First-order frame axiom

As an example of validating the subtyping axioms, we consider $\chi_1 \rightarrow \chi_2 \leq \chi_1 * C \rightarrow \chi_2 * C$.

Lemma 27. *Let $f_1, f_2 \in MT$ and $p \in Cap$, and let $w \in W$. Suppose that $(k, \text{fun } f(y)=t) \in (f_1 \rightarrow f_2)(w)$. Then $(k, \text{fun } f(y)=t) \in (f_1 * p \rightarrow f_2 * p)(w)$.*

Proof. By unfolding the definitions, and instantiating the universally quantified $r \in UPred(Heap)$ accordingly. The proof then relies on the fact that $p(w \circ w') \subseteq p(w \circ w' \circ w'')$ holds for all w', w'' in W , since $w \circ w' \in W$ and $p \in Cap$. \square

B.20 Semantics of typing judgements

Recall that we have two kinds of judgments, one for typing of values and the other for the typing of expressions:

$$\Delta \vdash v : \tau \qquad \Gamma \Vdash t : \chi$$

The semantics of a value judgement simply establishes truth with respect to all worlds w , all environments η and all $k \in \mathbb{N}$:

$$\models (\Delta \vdash v : \tau) \stackrel{\text{def}}{\iff} \forall \eta. \forall w \in W. \forall k \in \mathbb{N}. \forall (k, \rho) \in \llbracket \Delta \rrbracket_\eta w. (k, \rho(v)) \in \llbracket \tau \rrbracket_\eta w .$$

Here $\rho(v)$ means the application of the substitution ρ to v . The judgement for expressions mirrors the interpretation of the arrow case for value types, in that there is also a quantification over heap predicates $r \in UPred(Heap)$ and an existential quantification over $w' \in W$ through the use of \mathcal{E} :

$$\begin{aligned} \models (\Gamma \Vdash t : \chi) &\stackrel{\text{def}}{\iff} \forall \eta. \forall w \in W. \forall k \in \mathbb{N}. \forall r \in UPred(Heap). \\ &\forall (k, (\rho, h)) \in \llbracket \Gamma \rrbracket_\eta w * \iota^{-1}(w)(emp) * r. (k, (\rho(t), h)) \in \mathcal{E}(\llbracket \chi \rrbracket_\eta * r)(w) . \end{aligned}$$

The universal quantifications allow us to have frame rules: the universal quantification over worlds w ensures the soundness of the deep frame rule, and the universal quantification over heap predicates r validates the shallow frame rule, as we show next. The existential quantifier plays an important part in the verification of the anti-frame rule below.

B.21 Shallow frame rule

Soundness of the shallow frame rule is proved analogously to the soundness of the first-order frame axiom. In particular, it is essential that $\llbracket C \rrbracket \in Cap$ below:

Lemma 28. *Suppose $\models (\Gamma \Vdash t : \chi)$. Then $\models (\Gamma * C \Vdash t : \chi * C)$.*

B.22 Deep frame rule

Lemma 29. *Suppose $\models (\Gamma \Vdash t : \chi)$. Then $\models (\Gamma \otimes C * C \Vdash t : \chi \otimes C * C)$.*

Proof. We prove $\models (\Gamma \otimes C * C \Vdash t : \chi \otimes C * C)$. Let $w \in W$, $k \in \mathbb{N}$, $r \in \text{UPred}(\text{Heap})$ and

$$\begin{aligned} (k, (\rho, h)) &\in \llbracket \Gamma \otimes C * C \rrbracket (w) * \iota^{-1}(w)(\text{emp}) * r \\ &= \llbracket \Gamma \rrbracket (\iota(\llbracket C \rrbracket) \circ w) * \iota^{-1}(\iota(\llbracket C \rrbracket) \circ w)(\text{emp}) * r . \end{aligned}$$

Since $\llbracket C \rrbracket \in \text{Cap}$ we can instantiate $\models (\Gamma \Vdash t : \chi)$ with the world $w' = \iota(\llbracket C \rrbracket) \circ w$ to obtain $(k, (\rho(t), h)) \in \mathcal{E}(\llbracket \chi \rrbracket * r)(w')$. The latter is equivalent to $(k, (\rho(t), h)) \in \mathcal{E}(\llbracket \chi \otimes C * C \rrbracket * r)(w)$. \square

B.23 Anti-frame rule

Our soundness proof of the anti-frame rule employs the technique of so-called commutative pairs. This idea had already been present in Pottier's syntactic proof sketch [13], and has been worked out in more detail in [17].

Lemma 30. *For all worlds $w_0, w_1 \in W$, there exist $w'_0, w'_1 \in W$ such that*

$$w'_0 = \iota(\iota^{-1}(w_0) \otimes w'_1), \quad w'_1 = \iota(\iota^{-1}(w_1) \otimes w'_0), \quad \text{and} \quad w_0 \circ w'_1 = w_1 \circ w'_0 .$$

Proof. Fix $w_0, w_1 \in W$, and define a function F on $X \times X$ defined by

$$F(x'_0, x'_1) = (\iota(\iota^{-1}(w_0) \otimes x'_1), \iota(\iota^{-1}(w_1) \otimes x'_0)) .$$

Then, F is contractive, since \otimes is contractive in its right argument. Also, F restricts to a function on the non-empty and closed subset $W \times W$ of $X \times X$. Thus, by Banach's fixpoint theorem, there exists a unique fixpoint w'_0 and w'_1 of F . This means that

$$w'_0 = \iota(\iota^{-1}(w_0) \otimes w'_1) \quad \text{and} \quad w'_1 = \iota(\iota^{-1}(w_1) \otimes w'_0). \quad (49)$$

Note that these are the first two equalities claimed by this lemma. The remaining claim is $w_0 \circ w'_1 = w_1 \circ w'_0$, and it can be proved as follows. Let $w \in X$.

$$\begin{aligned} \iota^{-1}(w_0 \circ w'_1)(w) &= \iota^{-1}(w_0)(w'_1 \circ w) * \iota^{-1}(w'_1)(w) && \text{(by definition of } \circ \text{)} \\ &= (\iota^{-1}(w_0) \otimes w'_1)(w) * \iota^{-1}(w'_1)(w) && \text{(by definition of } \otimes \text{)} \\ &= \iota^{-1}(w'_0)(w) * (\iota^{-1}(w_1) \otimes w'_0)(w) && \text{(by (49))} \\ &= \iota^{-1}(w'_0)(w) * \iota^{-1}(w_1)(w'_0 \circ w) && \text{(by definition of } \otimes \text{)} \\ &= \iota^{-1}(w_1)(w'_0 \circ w) * \iota^{-1}(w'_0)(w) && \text{(by commutativity of } * \text{)} \\ &= \iota^{-1}(w_1 \circ w'_0)(w) && \text{(by definition of } \circ \text{)}. \end{aligned}$$

Since w was chosen arbitrarily, we have $\iota^{-1}(w_0 \circ w'_1) = \iota^{-1}(w_1 \circ w'_0)$, and the claim follows from the injectivity of ι^{-1} . \square

Lemma 31. *Suppose $\models (\Gamma \otimes C \Vdash t : \chi \otimes C * C)$. Then $\models (\Gamma \Vdash t : \chi)$.*

Proof. We prove $\models (\Gamma \Vdash t : \chi)$. Let $w \in W$, $k \in \mathbb{N}$, $r \in \text{UPred}(\text{Heap})$ and

$$(k, (\rho, h)) \in \llbracket \Gamma \rrbracket (w) * \iota^{-1}(w)(\text{emp}) * r .$$

We must prove $(k, (\rho(t), h)) \in \mathcal{E}(\llbracket \chi \rrbracket * r)(w)$.

By Lemma 30, there exist worlds w_1, w_2 in W such that

$$w_1 = \iota(\iota^{-1}(w) \otimes w_2), \quad w_2 = \iota(\llbracket C \rrbracket \otimes w_1) \quad \text{and} \quad \iota(\llbracket C \rrbracket) \circ w_1 = w \circ w_2 . \quad (50)$$

First, we find a superset of the precondition $\llbracket \Gamma \rrbracket (w) * \iota^{-1}(w)(\text{emp}) * r$ in the assumption above. Specifically, we replace the first two $*$ -conjuncts in the precondition by supersets as follows:

$$\begin{aligned} \llbracket \Gamma \rrbracket (w) &\subseteq \llbracket \Gamma \rrbracket (w \circ w_2) && \text{(by monotonicity of } \llbracket \Gamma \rrbracket \text{ and } w_2 \in W) \\ &= \llbracket \Gamma \rrbracket (\iota(\llbracket C \rrbracket) \circ w_1) && \text{(since } \iota(\llbracket C \rrbracket) \circ w_1 = w \circ w_2) \\ &= \llbracket \Gamma \otimes C \rrbracket (w_1) && \text{(by definition of } \otimes). \end{aligned}$$

$$\begin{aligned} \iota^{-1}(w)(\text{emp}) &\subseteq \iota^{-1}(w)(\text{emp} \circ w_2) && \text{(by monotonicity of } \iota^{-1}(w) \text{ and } w_2 \in W) \\ &= \iota^{-1}(w)(w_2 \circ \text{emp}) && \text{(since } \text{emp} \text{ is the unit)} \\ &= (\iota^{-1}(w) \otimes w_2)(\text{emp}) && \text{(by definition of } \otimes) \\ &= \iota^{-1}(w_1)(\text{emp}) && \text{(since } w_1 = \iota(\iota^{-1}(w) \otimes w_2)) \end{aligned}$$

Thus, we have that

$$(k, (\rho, h)) \in \llbracket \Gamma \rrbracket (w) * \iota^{-1}(w)(\text{emp}) * r \subseteq \llbracket \Gamma \otimes C \rrbracket (w_1) * \iota^{-1}(w_1)(\text{emp}) * r . \quad (51)$$

By the assumed validity of the judgement $\Gamma \otimes C \Vdash t : \chi \otimes C * C$, (51) entails

$$(k, (\rho(t), h)) \in \mathcal{E}(\llbracket \chi \otimes C * C \rrbracket * r)(w_1) . \quad (52)$$

We need to show that $(k, (\rho(t), h)) \in \mathcal{E}(\llbracket \chi \rrbracket * r)(w)$, so assume $(\rho(t) \mid h) \mapsto^j (t' \mid h')$ for some $j \leq k$ such that $(t' \mid h')$ is irreducible. From (52) we then obtain

$$(k-j, (t', h')) \in \bigcup_{w'} \llbracket \chi \otimes C * C \rrbracket (w_1 \circ w') * \iota^{-1}(w_1 \circ w')(\text{emp}) * r . \quad (53)$$

Now note that we have

$$\begin{aligned} &\llbracket \chi \otimes C * C \rrbracket (w_1 \circ w') * \iota^{-1}(w_1 \circ w')(\text{emp}) \\ &= \llbracket \chi \rrbracket (\iota(\llbracket C \rrbracket) \circ w_1 \circ w') * \llbracket C \rrbracket (w_1 \circ w') * \iota^{-1}(w_1 \circ w')(\text{emp}) \\ &= \llbracket \chi \rrbracket (\iota(\llbracket C \rrbracket) \circ w_1 \circ w') * \iota^{-1}(\iota(\llbracket C \rrbracket) \circ w_1 \circ w')(\text{emp}) \\ &= \llbracket \chi \rrbracket (w \circ w'') * \iota^{-1}(w \circ w'')(\text{emp}) \end{aligned}$$

for $w'' \stackrel{\text{def}}{=} w_2 \circ w'$, since $w \circ w_2 = \iota(\llbracket C \rrbracket) \circ w_1$. Thus, (53) entails

$$(k-j, (t', h')) \in \bigcup_{w''} \llbracket \chi \rrbracket (w \circ w'') * \iota^{-1}(w \circ w'')(\text{emp}) * r ,$$

and we are done. \square

C Generalized Frame and Anti-frame Rules

In this section we consider the extension of the previous model to the *generalized* frame and anti-frame rules of Pottier's [14]. We begin by solving the equation

$$X \cong \sum_{\alpha \in \mathcal{K}^*} X_\alpha, \quad X_{\kappa_1, \dots, \kappa_n} = (\kappa_1 \times \dots \times \kappa_n) \rightarrow (\frac{1}{2} \cdot X \rightarrow UPred(Heap)), \quad (54)$$

with isomorphism $\iota : \sum_{\alpha \in \mathcal{K}^*} X_\alpha \rightarrow X$ in $CBUlt_{ne}$, where each $\kappa \in \mathcal{K}$ is equipped with the discrete metric. Next, we define the (recursive) composition operation $\circ : X \times X \rightarrow X$ as follows.

Lemma 32. *There exists a non-expansive operation $\circ : X \times X \rightarrow X$ satisfying $x_1 \circ x_2 = \iota(\langle \alpha_1 \alpha_2, p \rangle)$, where $\langle \alpha_i, p_i \rangle = \iota^{-1}(x_i)$ for $i = 1, 2$, and where $p \in X_{\alpha_1 \alpha_2}$ is defined by*

$$p(i_1 i_2)(x) = p_1(i_1)(x_2 \circ x) * p_2(i_2)(x).$$

for all $i_1 \in \alpha_1, i_2 \in \alpha_2$.

Proof (sketch). The operation is obtained as the (unique) fixed point of a contractive functional F on the metric space $X^{X \times X}$, by the Banach fixed point theorem. It maps an operation $\bullet \in X^{X \times X}$ and x_1, x_2 (with $\langle \alpha_i, p_i \rangle = \iota^{-1}(x_i)$ for $i = 1, 2$) to $z \in X$, given by $z = \iota(\langle \alpha_1 \alpha_2, p \rangle)$,

$$p(i_1 i_2)(x) = p_1(i_1)(x_2 \bullet x) * p_2(i_2)(x).$$

for all $i_1 \in \alpha_1, i_2 \in \alpha_2$. It is straightforward to check that $F(\bullet)$ is non-expansive (i.e., it is in $X^{X \times X}$), and that F is contractive (i.e., that $\bullet_1 \stackrel{n}{=} \bullet_2$ implies $F(\bullet_1) \stackrel{n \pm 1}{=} F(\bullet_2)$). \square

Lemma 33. *\circ is associative, and has a unit given by $\text{emp} = \iota(\langle \varepsilon, \lambda, \dots, I \rangle)$.*

C.1 Equivalence relation \sim on recursive worlds

We consider a (partial) equivalence relation \sim on X as follows. Given $x, y \in X$ such that $\iota^{-1}(x) = \langle \alpha, p \rangle$ and $\iota^{-1}(y) = \langle \beta, q \rangle$, then $x \sim y$ holds if and only if

- there exists $n \in \mathbb{N}$ and a permutation π of $1, \dots, n$ such that $\alpha = \alpha_1 \dots \alpha_n$ and $\beta = \alpha_{\pi(1)} \dots \alpha_{\pi(n)}$; and
- for all $i_1 \in \alpha_1, \dots, i_n \in \alpha_n$ and $z \sim z'$, $p(i_1 \dots i_n)(z) = q(i_{\pi(1)} \dots i_{\pi(n)})(z')$.

Note that this relation is recursive. Formally, it is defined as the fixed point of a contractive function $\Psi : \mathcal{R}(X \times X) \rightarrow \mathcal{R}(X \times X)$ on the non-empty and closed subsets of $X \times X$:

Definition 34. *Let $\Psi : \mathcal{R}(X \times X) \rightarrow \mathcal{R}(X \times X)$ be defined by $(x, y) \in \Psi(R)$ if and only if*

- there exists $n \in \mathbb{N}$ and a permutation π of $1, \dots, n$ such that $\alpha = \alpha_1 \dots \alpha_n$ and $\beta = \alpha_{\pi(1)} \dots \alpha_{\pi(n)}$; and
- for all $i_1 \in \alpha_1, \dots, i_n \in \alpha_n$ and all $z, z' \in X$, if $(z, z') \in R$ then $p(i_1 \dots i_n)(z) = q(i_{\pi(1)} \dots i_{\pi(n)})(z')$.

Since $(\text{emp}, \text{emp}) \in \Psi(R)$, and if $(x_k, y_k)_k$ is a Cauchy chain in $\Psi(R)$ then the limit $(\lim x_k, \lim y_k)$ is also in $\Psi(R)$ as it is given pointwise:

$$\begin{aligned} (\lim_k p_k)(i_1 \dots i_n)(z) &= \lim_k p_k(i_1 \dots i_n)(z) \\ &= \lim_k q_k(i_{\pi(1)} \dots i_{\pi(n)})(z') = (\lim_k q_k)(i_{\pi(1)} \dots i_{\pi(n)})(z'). \end{aligned}$$

Thus, we indeed have $\Psi(R) \in \mathcal{R}(X \times X)$. Moreover, Ψ is contractive, i.e., $R \stackrel{n}{=} S$ in $\mathcal{R}(X \times X)$ implies $\Psi(R) \stackrel{n+1}{=} \Psi(S)$; the proof of this fact is similar to proof of Lemma 12.

As a consequence, we can define $\sim \subseteq X \times X$ as the unique fixed point of Ψ by the Banach fixed point theorem.

Lemma 35. \sim is a partial equivalence relation on X :

- $x \sim y$ implies $y \sim x$;
- $x \sim y$ and $y \sim z$ implies $x \sim z$.

Proof. Since $(\sim_{[n]})_n$ is a Cauchy chain in $\mathcal{R}(X \times X)$ with limit \sim given as the intersection of the $\sim_{[n]}$, part 1 follows from the claim:

$$\forall nxy. x \sim y \Rightarrow (y, x) \in \sim_{[n]},$$

which is proved by induction on n .

The case $n = 0$ is immediate since $\sim_{[0]} = X \times X$. For the case $n > 0$ let $x \sim y$. For simplicity, we assume $x = \iota\langle \alpha_1 \alpha_2, p \rangle$ and $y = \iota\langle \alpha_2 \alpha_1, q \rangle$. To prove $(y, x) \in \sim_{[n]}$ it suffices to show that $y' \sim x'$ holds for $y' = \iota\langle \alpha_2 \alpha_1, q' \rangle$ and $x' = \iota\langle \alpha_1 \alpha_2, p' \rangle$ with $q'(i_2 i_1)(z) = q(i_2 i_1)(z)_{[n]}$ and $p'(i_1 i_2)(z) = p(i_1 i_2)(z)_{[n]}$, since $(y, x) \stackrel{n}{=} (y', x')$. To this end, let $i_2 \in \alpha_2$, $i_1 \in \alpha_1$, and suppose that $z \sim z'$; we must prove $q'(i_2 i_1)(z) = p'(i_1 i_2)(z')$. By induction hypothesis, $(z', z) \in \sim_{[n-1]}$, i.e., there exists $u' \sim u$ with $u' \stackrel{n-1}{=} z'$ and $u \stackrel{n-1}{=} z$ in X . Note that this means $u' \stackrel{n}{=} z'$ and $u \stackrel{n}{=} z$ holds in $\frac{1}{2} \cdot X$. Thus:

$$q(i_2 i_1)(z) \stackrel{n}{=} q(i_2 i_1)(u) = p(i_1 i_2)(u') \stackrel{n}{=} p(i_1 i_2)(z')$$

by the non-expansiveness of p, q , and by the assumption $x \sim y$. It follows that

$$q'(i_2 i_1)(z) = q(i_2 i_1)(z)_{[n]} = p(i_1 i_2)(u')_{[n]} = p'(i_1 i_2)(z')$$

i.e., we have shown $y' \sim x'$.

Part 2 follows from a similar argument, proving that for all n , $x \sim y$ and $y \sim z$ implies $(x, z) \in \sim_{[n]}$. \square

Lemma 36. *Composition respects \sim , so if $x \sim x'$ and $y \sim y'$ then $x \circ y \sim x' \circ y'$.*

Proof. Similar to the proof of Lemma 4: We prove that for all $n \in \mathbb{N}$,

$$x \sim x', y \sim y' \Rightarrow (x \circ y, x' \circ y') \in \sim_{[n]}$$

by induction on n , and then use that \sim is the intersection of all the $\sim_{[n]}$. \square

C.2 Hereditarily monotonic recursive worlds

Next, we define the hereditarily monotonic worlds. We make sure that these worlds w respect \sim (which means that they are self-related, $w \sim w$): we aim for a set $W \subseteq X$ such that $w \in W$ for $\iota^{-1}(w) = \langle \alpha, p \rangle$ holds iff

$$(1) w \sim w \text{ and } (2) \forall i \in \alpha, w_1, w_2 \in W. p(i)(w_1) \subseteq p(i)(w_1 \circ w_2)$$

The set W is again defined as fixed point of a contractive function Φ , on the closed and non-empty subsets of X : Consider $\Phi : \mathcal{P}(X) \rightarrow \mathcal{P}(X)$, with $w \in \Phi(R)$ if and only if

- $w \sim w$; and
- whenever $w = \iota \langle \alpha, p \rangle, i \in \alpha, w_1, w_2 \in R$ then $p(i)(w_1) \subseteq p(i)(w_1 \circ w_2)$.

Lemma 37. *Φ restricts to a contractive function on $\mathcal{R}(X)$.*

Thus, we can define the hereditarily monotonic functions $W = \text{fix}(\Phi) = \Phi(W)$ by the Banach fixed point theorem.

Proof (sketch). The proof is along the lines of Lemma 12 in the case of the non-parameterized worlds. \square

Lemma 38. *If $w_1, w_2 \in W$ then $w_1 \circ w_2 \in W$.*

Proof (sketch). Similar to the proof of Lemma 4: We prove that for all $n \in \mathbb{N}$,

$$x, y \in W \Rightarrow x \circ y \in W_{[n]}$$

by induction on n . Lemma 36 is used to show the additional requirement that the composition of $x, y \in W$ is self-related, $x \circ y \sim x \circ y$. \square

We can check that the hereditarily monotonic worlds are closed under \sim .

Lemma 39. *Suppose $w \sim w'$ and $w \in W$. Then $w' \in W$.*

Proof. We prove that $w' \in \Phi(W) = W$. By symmetry and transitivity of \sim we obtain $w' \sim w$ from $w \sim w'$. Next, assume for simplicity that $\iota^{-1}(w) = \langle \alpha_1 \alpha_2, p \rangle$ and $\iota^{-1}(w') = \langle \alpha_2 \alpha_1, p' \rangle$. Let $i_2 \in \alpha_2, i_1 \in \alpha_1$, and $w_1, w_2 \in W$. In particular, $w_1 \sim w_1$ and $w_2 \sim w_2$. Then $w \in W$ gives

$$p'(i_2 i_1)(w_1) = p(i_1 i_2)(w_1) \subseteq p(i_1 i_2)(w_1 \circ w_2) = p'(i_2 i_1)(w_1 \circ w_2)$$

where the last equality holds since $w_1 \circ w_2 \sim w_1 \circ w_2$, by $w_1 \sim w_1, w_2 \sim w_2$, and Lemma 36. \square

C.3 Semantic domains

The semantic domains for the capabilities and types, with respect to the generalized worlds, now consist of the world-dependent functions that are both monotonic (with respect to the hereditarily monotonic worlds) and respect \sim . More precisely, for a preordered set A we define $\frac{1}{2} \cdot W \rightarrow_{mon} UPred(A)$ to consist of all those $p : \frac{1}{2} \cdot X \rightarrow UPred(A)$ where

- $\forall x, x' \in X. x \sim x' \Rightarrow p(x) = p(x')$;
- $\forall w_1, w_2 \in W. p(w_1) \subseteq p(w_1 \circ w_2)$.

Then we set

$$\begin{aligned} Cap &= \frac{1}{2} \cdot W \rightarrow_{mon} UPred(Heap) \\ VT &= \frac{1}{2} \cdot W \rightarrow_{mon} UPred(Val) \\ MT &= \frac{1}{2} \cdot W \rightarrow_{mon} UPred(Val \times Heap) , \end{aligned}$$

Note that $p \in \kappa \rightarrow Cap$ if and only if $\iota(\langle \kappa, p \rangle) \in W$. Also note that, by definition of the metric on X , $x \stackrel{n}{\approx} x'$ for $n > 0$ implies that for $\langle \alpha, p \rangle$ and $\langle \alpha', p' \rangle$ we have $\alpha = \alpha'$ and $p i \stackrel{n}{\approx} p' i$ for all $i \in \alpha$.

C.4 Extension to expressions

We define the following extension of memory types from values to expressions.

Definition 40 (Expression typing). *Let T in $\frac{1}{2} \cdot W \rightarrow_{mon} UPred(Val \times Heap)$. Let $x \in X$ and $\langle \alpha, p \rangle = \iota^{-1}(x)$. Let $i \in \alpha$. Then $\mathcal{E}(T, x, i) \subseteq Exp \times Heap$ is defined by $(k, (t, h)) \in \mathcal{E}(T, x, i)$ if and only if*

$$\begin{aligned} &\forall j \leq k, t', h'. (t | h) \mapsto^j (t' | h') \wedge (t' | h') \text{ irreducible} \\ &\Rightarrow (k-j, (t', h')) \in \bigcup_{w \in W, \langle \alpha\beta, q \rangle = \iota^{-1}(x \circ w), i_1 \geq i, i_2 \in \beta} T(x \circ w) * q(i_1 i_2)(emp) . \end{aligned}$$

Lemma 41. *With T, x, i as above, $\mathcal{E}(T, x, i)$ is a uniform subset of $Exp \times Heap$ (with respect to the discrete order on $Exp \times Heap$), and non-expansive as a function in x . Moreover, if $x' \sim x$ and i' is a corresponding reordering of the parameters i , then $\mathcal{E}(T, x', i') = \mathcal{E}(T, x, i)$.*

Proof. Uniformity follows directly from the definition. If $x \stackrel{n}{\approx} x'$ then $x \circ w \stackrel{n}{\approx} x' \circ w$ by the non-expansiveness of \circ . Using the non-expansiveness of T , the non-expansiveness of $\mathcal{E}(T, \cdot, \cdot)$ then follows.

For the last part, observe that $x \sim x'$ implies $x \circ w \sim x' \circ w$, and thus $T(x \circ w) = T(x' \circ w)$ since T is in $\frac{1}{2} \cdot W \rightarrow_{mon} UPred(Val \times Heap)$. Similarly, for all parameters $i_1 \geq i$ there exists a corresponding reordering $i'_1 \geq i'$, and then $\iota^{-1}(x' \circ w)(i'_1 i_2)(emp) = \iota^{-1}(x \circ w)(i_1 i_2)(emp)$ since $emp \sim emp$. \square

C.5 Closure of VT under arrow types

The definition of function types changes as follows: given $x \in X$, $(k, \text{fun } f(y)=t) \in (T_1 \rightarrow T_2)(x)$ if and only if

$$\begin{aligned} & \forall j < k. \forall w \in W \text{ where } \iota^{-1}(x \circ w) = \langle \alpha, p \rangle. \forall r \in \text{UPred}(\text{Heap}). \forall i \in \alpha. \\ & \forall (j, (v, h)) \in T_1(x \circ w) * p(i)(\text{emp}) * r. \\ & (j, t[f:=\text{fun } f(y)=t, y:=v], h) \in \mathcal{E}(T_2 * r, x \circ w, i) , \end{aligned}$$

using the above extension of T_2 to expressions.

Lemma 42. *For $T_1, T_2 \in MT$, $T_1 \rightarrow T_2$ is non-expansive, and $(T_1 \rightarrow T_2)(x)$ is uniform for all $x \in X$. Moreover, $T_1 \rightarrow T_2 \in VT$, and the assignment of $T_1 \rightarrow T_2$ to T_1, T_2 is contractive.*

Proof. The non-expansiveness follows from Lemma 41 (and analogous reasoning for the function argument from T_1). The uniformity is ensured by the explicit quantification over $j < k$ in the definition of $(T_1 \rightarrow T_2)(x)$.

$T_1 \rightarrow T_2$ respects \sim , since the parameters are all universally quantified. More precisely, let $x \sim x'$. Then $x \circ w \sim x' \circ w$ by Lemma 36. Assume that $\iota^{-1}(x \circ w) = \langle \alpha_1 \alpha_2, p \rangle$ and $\iota^{-1}(x' \circ w) = \langle \alpha_2 \alpha_1, p' \rangle$. Then for all $i_1 i_2 \in \alpha_1 \alpha_2$ we have $p(i_1 i_2)(\text{emp}) = p'(i_2 i_1)(\text{emp})$ since $\text{emp} \sim \text{emp}$, and also $T_1(x \circ w) = T_1(x' \circ w)$ since $T_1 \in MT$. Further, $\mathcal{E}(T_2 * r, x \circ w, i_1 i_2) = \mathcal{E}(T_2 * r, x' \circ w, i_2 i_1)$ by Lemma 41. Also, the quantification over worlds $w \in W$, together with the closure of W under \circ , ensures that $T_1 \rightarrow T_2$ satisfies the monotonicity condition $(T_1 \rightarrow T_2)(w_1) \subseteq (T_1 \rightarrow T_2)(w_1 \circ w_2)$, and hence $T_1 \rightarrow T_2$ is in VT .

Finally, the contractiveness of $(\cdot \rightarrow \cdot)$ follows since the k -th level of $(T_1 \rightarrow T_2)$ is determined by considering both $T_1(x \circ w)$ and $\mathcal{E}(T_2 * r, x \circ w, i)$ only up to level j strictly smaller than k . \square

C.6 Distribution of \otimes over \rightarrow

The following lemma yields the key property to validate the syntactic distribution axiom for the generalized invariants.

Lemma 43. *Let $T_1, T_2 \in MT$, and let $w \in W$ with $\langle \alpha, p \rangle = \iota^{-1}(w)$. Then*

$$(T_1 \rightarrow T_2) \otimes w = \forall_{i \in \alpha} ((T_1 \otimes w) * p i) \rightarrow \exists_{i' \geq i} ((T_2 \otimes w) * p i') .$$

where \forall and \exists mean the pointwise intersection and union of world-indexed uniform predicates.

Proof. The proof is analogous to the one of Lemma 25, taking some care of the indices i and i' . Let $x \in X$ and

$$(k, (\text{fun } f(y)=t)) \in ((T_1 \rightarrow T_2) \otimes w)(x) = (T_1 \rightarrow T_2)(w \circ x) .$$

We must prove that $(k, (\text{fun } f(y)=t)) \in \forall_i(T_1 \otimes w * p i) \rightarrow \exists_{i' \geq i}(T_2 \otimes w * p i')$. To this end, fix $i \in \alpha$, let $j < k$, let $w_1 \in W$ (where $\iota^{-1}(x \circ w_1) = \langle \alpha_1, p_1 \rangle$), let $i_1 \in \alpha_1$, let $r \in \text{UPred}(\text{Heap})$, and suppose

$$\begin{aligned} (j, (v, h)) &\in (T_1 \otimes w * p i)(x \circ w_1) * \iota^{-1}(x \circ w_1)(i_1)(\text{emp}) * r \\ &= T_1(w \circ x \circ w_1) * p(i)(x \circ w_1) * \iota^{-1}(x \circ w_1)(i_1)(\text{emp}) * r \\ &= T_1(w \circ x \circ w_1) * \iota^{-1}(w \circ x \circ w_1)(ii_1)(\text{emp}) * r . \end{aligned}$$

Then, by the assumption, $(j, (t[f:=\text{fun } f(y)=t, y:=v], h)) \in \mathcal{E}(T_2 * r, w \circ x \circ w_1, ii_1)$. Unfolding the definition of \mathcal{E} , $\mathcal{E}(T_2 * r, w \circ x \circ w_1, ii_1)$ is seen to be equivalent to $\mathcal{E}(\exists_{i' \geq i} T_2 \otimes w * p i' * r, x \circ w_1, i_1)$, because we have

$$\begin{aligned} &\bigcup_{w_2, i_2, i' i_1 \geq ii_1} T_2(w \circ x \circ w_1 \circ w_2) * q(i' i_1 i_2)(\text{emp})(\text{emp}) * r \\ &= \bigcup_{w_2, i_2, i' i_1 \geq ii_1} (T_2 \otimes w * p(i'))(x \circ w_1 \circ w_2) * q_1(i' i_1 i_2)(\text{emp}) * r \\ &= \bigcup_{w_2, i_2, i_1' \geq i_1} \left(\bigcup_{i' \geq i} (T_2 \otimes w * p(i'))(x \circ w_1 \circ w_2) \right) * q_1(i_1' i_2)(\text{emp}) * r \\ &= \bigcup_{w_2, i_2, i_1' \geq i_1} (\exists_{i' \geq i} (T_2 \otimes w * p(i')))(x \circ w_1 \circ w_2) * q_1(i_1' i_2)(\text{emp}) * r \end{aligned}$$

for $\iota^{-1}(x \circ w_1 \circ w_2) = \langle \alpha_1 \beta, q_1 \rangle$ and $\iota^{-1}(w \circ x \circ w_1 \circ w_2) = \langle \alpha \alpha_1 \beta, q \rangle$.

The other direction is similar. \square

C.7 Semantics of typing judgements

The semantics of value judgement looks as before, i.e., it establishes truth with respect to all worlds w , all environments η and all $k \in \mathbb{N}$:

$$\models (\Delta \vdash v : \tau) \stackrel{\text{def}}{\iff} \forall \eta. \forall w \in W. \forall k \in \mathbb{N}. \forall (k, \rho) \in \llbracket \Delta \rrbracket_\eta w. (k, \rho(v)) \in \llbracket \tau \rrbracket_\eta w .$$

The judgement for expressions again mirrors the interpretation of the arrow case for value types, in that there now is also a universal quantification over all possible instances of the invariants represented by the world $w \in W$:

$$\begin{aligned} \models (\Gamma \Vdash t : \chi) &\stackrel{\text{def}}{\iff} \forall \eta. \forall w \in W \text{ where } w = \langle \alpha, p \rangle. \forall k \in \mathbb{N}. \\ &\forall i \in \alpha. \forall r \in \text{UPred}(\text{Heap}). \forall (k, (\rho, h)) \in \llbracket \Gamma \rrbracket_\eta w * p(i)(\text{emp}) * r. \\ &(k, (\rho(t), h)) \in \mathcal{E}(\llbracket \chi \rrbracket_\eta * r, w, i). \end{aligned}$$

C.8 Generalized frame rule

Lemma 44. *Suppose $\models (\Gamma \Vdash t : \chi)$. Assume that I has kind $\kappa \rightarrow \text{CAP}$ (and thus $\llbracket I \rrbracket : \kappa \rightarrow \text{Cap}$), and that $i \in \kappa$. Then $\models (\Gamma \otimes I * I i \Vdash t : \exists j \geq i. ((\chi \otimes I) * I j))$.*

Proof. We prove $\models (\Gamma \otimes I * I i \Vdash t : \exists j \geq i. ((\chi \otimes I) * I j))$. Let $w \in W$ with $\langle \alpha, p \rangle$, let $i_1 \in \alpha$, let $k \in \mathbb{N}$, let $r \in UPred(Heap)$ and let

$$(k, (\rho, h)) \in \llbracket \Gamma \otimes I * I i \rrbracket (w) * p(i_1)(emp) * r$$

Since $\llbracket I \rrbracket : \kappa \rightarrow Cap$ we know that $w' \stackrel{def}{=} \iota \langle \kappa, \llbracket I \rrbracket \rangle \circ w$ is in W . Moreover, $w' = \iota \langle \kappa \alpha, p' \rangle$ where $p'(ii_1)(x) = \llbracket I \rrbracket (i)(w \circ x) * p(i_1)(x)$, and thus

$$\begin{aligned} & \llbracket \Gamma \otimes I * I i \rrbracket (w) * p(i_1)(emp) * r \\ &= \llbracket \Gamma \rrbracket (\iota \langle \kappa, \llbracket I \rrbracket \rangle \circ w) * \llbracket I \rrbracket (i)(w) * p(i_1)(emp) * r \\ &= \llbracket \Gamma \rrbracket (w') * p'(ii_1)(emp) * r . \end{aligned}$$

Since $w' \in W$ we can instantiate $\models (\Gamma \Vdash t : \chi)$ to obtain $(k, (\rho(t), h)) \in \mathcal{E}(\llbracket \chi \rrbracket * r, w', ii_1)$. As in the proof of Lemma 43, the latter is shown to be equivalent to the statement

$$(k, (\rho(t), h)) \in \mathcal{E}(\exists_{j \geq i} \llbracket \chi \otimes I * I j \rrbracket * r, w, i_1) = \mathcal{E}(\llbracket \exists j \geq i. (\chi \otimes I) * I j \rrbracket * r, w, i_1)$$

and this establishes $\models (\Gamma \otimes I * I i \Vdash t : \exists j \geq i. ((\chi \otimes I) * I j))$. \square

C.9 Generalized anti-frame rule

As before, the soundness proof of the anti-frame rule rests on the existence of commutative pairs. For the generalized invariants, the statement is a variant of the earlier Lemma 30, stating that “commutativity” is up to the relation \sim :

Lemma 45. *Let $w_0, w_1 \in W$ be families indexed over α_0 and α_1 , i.e., $\iota^{-1}(w_0) = \langle \alpha_0, p_0 \rangle$ and $\iota^{-1}(w_1) = \langle \alpha_1, p_1 \rangle$. Then there exist $w'_0, w'_1 \in W$ such that*

$$\begin{aligned} w'_0 &= \iota \langle \alpha_0, \lambda i. (p_0 i) \otimes w'_1 \rangle, \\ w'_1 &= \iota \langle \alpha_1, \lambda i. (p_1 i) \otimes w'_0 \rangle, \text{ and} \\ w_0 \circ w'_1 &\sim w_1 \circ w_0 . \end{aligned}$$

Proof. The existence of commutative pairs in the above sense is proved as in Lemma 30, modulo the indexing over α_0 and α_1 , respectively. \square

Lemma 46. *Assume that I has kind $\kappa \rightarrow CAP$, and suppose that we have $\models (\Gamma \otimes I \Vdash t : (\chi \otimes I) * \exists i. I i)$. Then $\models (\Gamma \Vdash t : \chi)$.*

Proof. We prove $\models (\Gamma \Vdash t : \chi)$. Let $w \in W$ with $\iota^{-1}(w) = \langle \alpha, p \rangle$, $i \in \alpha$, $k \in \mathbb{N}$, $r \in UPred(Heap)$ and

$$(k, (\rho, h)) \in \llbracket \Gamma \rrbracket (w) * p(i)(emp) * r .$$

We must prove $(k, (\rho(t), h)) \in \mathcal{E}(\llbracket \chi \rrbracket * r, w, i)$. By Lemma 45, there exist worlds w_1, w_2 in W such that

$$\begin{aligned} w_1 &= \iota \langle \alpha, \lambda i. (p i) \otimes w_2 \rangle, \\ w_2 &= \iota \langle \kappa, \lambda i. (\llbracket I \rrbracket i) \otimes w_1 \rangle, \text{ and} \\ w \circ w_2 &\sim \iota \langle \kappa, \llbracket I \rrbracket \rangle \circ w_1 . \end{aligned} \tag{55}$$

As in Lemma 31 we now find a superset of the precondition $\llbracket \Gamma \rrbracket (w) * p(i)(emp) * r$ in the assumption above. Specifically, we replace the first two $*$ -conjuncts in the precondition by supersets as follows:

$$\begin{aligned}
\llbracket \Gamma \rrbracket (w) &\subseteq \llbracket \Gamma \rrbracket (w \circ w_2) && \text{(by monotonicity of } \llbracket \Gamma \rrbracket \text{ and } w_2 \in W) \\
&= \llbracket \Gamma \rrbracket (\iota \langle \kappa, \llbracket I \rrbracket \rangle \circ w_1) && \text{(since } \iota \langle \kappa, \llbracket I \rrbracket \rangle \circ w_1 \sim w \circ w_2) \\
&= \llbracket \Gamma \otimes I \rrbracket (w_1) && \text{(by definition of } \otimes). \\
p(i)(emp) &\subseteq p(i)(emp \circ w_2) && \text{(by monotonicity of } p(i) \text{ and } w_2 \in W) \\
&= p(i)(w_2 \circ emp) && \text{(since } emp \text{ is the unit)} \\
&= ((p(i)) \otimes w_2)(emp) && \text{(by definition of } \otimes).
\end{aligned}$$

(Note that we have used $\llbracket \Gamma \rrbracket : \frac{1}{2} \cdot W \rightarrow_{mon} UPred(Env \times Heap)$ in the first equality above.) Thus, we have that

$$(k, (\rho, h)) \in \llbracket \Gamma \rrbracket (w) * p(i)(emp) * r \subseteq \llbracket \Gamma \otimes I \rrbracket (w_1) * ((p(i)) \otimes w_2)(emp) * r. \quad (56)$$

By the assumed validity of the judgement $\Gamma \otimes I \Vdash t : \chi \otimes I * \exists i. I i$, (56) entails

$$(k, (\rho(t), h)) \in \mathcal{E}(\llbracket \chi \otimes I * \exists i_0. I i_0 \rrbracket * r, w_1, i). \quad (57)$$

We need to show that $(k, (\rho(t), h)) \in \mathcal{E}(\llbracket \chi \rrbracket * r, w, i)$, so assume $(\rho(t) \mid h) \mapsto^j (t' \mid h')$ for some $j \leq k$ such that $(t' \mid h')$ is irreducible. From (57) we then obtain

$$(k-j, (t', h')) \in \llbracket \chi \otimes I * \exists i_0. I i_0 \rrbracket (w_1 \circ w') * q(i_1 i_2)(emp) * r. \quad (58)$$

for some $w' \in W$, some $i_1 \geq i$ and some $i_2 \in \beta$, where $\iota^{-1}(w_1 \circ w') = \langle \alpha\beta, q \rangle$. Let us write $s(i_0 i_1 i_2)(x) \stackrel{def}{=} \llbracket I \rrbracket (i_0)(w_1 \circ w' \circ x) * q(i_1 i_2)(x)$, so that $\iota \langle \kappa \alpha \beta, s \rangle = \iota \langle \kappa, \llbracket I \rrbracket \rangle \circ (w_1 \circ w')$.

Now note that we have

$$\begin{aligned}
&\llbracket \chi \otimes I * \exists i_0. I i_0 \rrbracket (w_1 \circ w') * q(i_1 i_2)(emp) \\
&= \bigcup_{i_0} \llbracket \chi \rrbracket (\iota \langle \kappa, \llbracket I \rrbracket \rangle \circ w_1 \circ w') * \llbracket I \rrbracket (i_0)(w_1 \circ w') * q(i_1 i_2)(emp) \\
&= \bigcup_{i_0} \llbracket \chi \rrbracket (\iota \langle \kappa, \llbracket I \rrbracket \rangle \circ w_1 \circ w') * s(i_0 i_1 i_2)(emp)
\end{aligned}$$

If we write $w'' \stackrel{def}{=} w_2 \circ w'$ then, since $\iota \langle \kappa, \llbracket I \rrbracket \rangle \circ w_1 \sim w \circ w_2$, we have

$$\iota \langle \kappa, \llbracket I \rrbracket \rangle \circ w_1 \circ w' \sim w \circ w'' \quad (59)$$

by Lemma 36, and thus

$$\llbracket \chi \rrbracket (\iota \langle \kappa, \llbracket I \rrbracket \rangle \circ w_1 \circ w') = \llbracket \chi \rrbracket (w \circ w'').$$

Moreover, for s' such that $\iota^{-1}(w \circ w'') = \langle \alpha \kappa \beta, s' \rangle$, (59) and $emp \sim emp$ gives

$$s(i_0 i_1 i_2)(emp) = s'(i_1 i_0 i_2)(emp).$$

Thus, (58) entails

$$(k-j, (t', h')) \in \bigcup_{w'', i_0 i_2 \in \kappa \beta, i_1 > i} \llbracket \chi \rrbracket (w \circ w'') * s'(i_1 i_0 i_2)(emp) * r,$$

and we are done. \square
