

## Dictionaries and Sets

- dict
- set
- frozenset
- set/dict comprehensions

# Dictionaries (type dict)

{  $key_1$ :  $value_1$ , ...,  $key_k$ :  $value_k$  }

- Stores a mutable set of (key, value) pairs, denoted *items*, with distinct keys, i.e. *maps* keys to values
- Constructing empty dictionary: `dict()` or `{}`
- `dict[key]` lookup for key in dictionary, and returns associated value. Key must be present, otherwise a `KeyError` is raised
- `dict[key] = value` assigns value to key, overriding existing value if present

key	value
'a'	7
'foo'	'42nd'
5	29
'5'	44
5.5	False
False	True
(3, 4)	'abc'

distinct keys,  
i.e. not `"=="`

# Dictionaries (type dict)

## Python shell

```
> d = {'a': 42, 'b': 57}
> d
| {'a': 42, 'b': 57}

> d.keys()
| dict_keys(['a', 'b'])

> list(d.keys())
| ['a', 'b']

> d.items()
| dict_items([('a', 42), ('b', 57)])

> list(d.items())
| [('a', 42), ('b', 57)]
```

```
> for key in d:
    print(key)
| a
| b

> for key, val in d.items():
    print('Key', key, 'has value', val)
| Key a has value 42
| Key b has value 57

> {5: 'a', 5.0: 'b'}
| {5: 'b'}
```

## Python shell

```
> surname = dict(zip(['Donald', 'Mickey', 'Scrooge'], ['Duck', 'Mouse', 'McDuck']))
> surname['Mickey']
| 'Mouse'
```

# Dictionaries (type dict)

Python shell

```
> gradings = [('A', 7), ('B', 4), ('A', 12), ('C', 10), ('A', 7)]
> grades = {} # empty dictionary
> for student, grade in gradings:
    if student not in grades: # is key in dictionary
        grades[student] = []
        grades[student].append(grade)
> grades
| {'A': [7, 12, 7], 'B': [4], 'C': [10]}
> print(grades['A'])
| [7, 12, 7]
> print(grades['E']) # can only lookup keys in dictionary
| KeyError: 'E'
> print(grades.get('E')) # .get returns None if key not in dictionary
| None
> print(grades.get('E', [])) # change default return value
| []
> print(grades.get('A', []))
| [7, 12, 7]
```

# Dictionary initialization

Python shell

```
> d1 = {'A': 7, 'B': 42}
> d2 = dict([('A', 7), ('B', 42)])      # list of (key, value) pairs
> d3 = dict(A=7, B=42)                  # keyword arguments to constructor
> d1 == d2 == d3
| True
```

- Note: *keyword initialization* only works if keys are strings which are valid keyword arguments to a function – but saves writing a lot of quotes

Python shell

```
> d1 = dict(A=1, B=2)
> d2 = dict(B=3, C=4)
> d1 | d2                                # merge dictionaries
| {'A': 1, 'B': 3, 'C': 4}                 # rightmost value for 'B' wins
> **d1, **d2, 'D': 5                      # ** inserts dictionary content
| {'A': 1, 'B': 3, 'C': 4, 'D': 5}        # rightmost value for 'B' wins
> d1 |= d2                                # same as d1.update(d2)
> d1
| {'A': 1, 'B': 3, 'C': 4}
```

Python 3.9  
[PEP 584](#)

Dictionary operation	Description
<code>len(d)</code>	Items in dictionary
<code>d[key]</code>	Lookup key
<code>d[key] = value</code>	Update value of key
<code>del d[key]</code>	Delete an existing key
<code>key in d</code>	Key membership
<code>key not in d</code>	Key non-membership
<code>clear()</code>	Remove all items
<code>copy()</code>	Shallow copy
<code>get(key), get(key, default)</code>	<code>d[key]</code> if key in dictionary, otherwise <code>None</code> or <code>default</code>
<code>items()</code>	<i>View</i> of the dictionaries items
<code>keys()</code>	<i>View</i> of the dictionaries keys
<code>values()</code>	<i>View</i> of the dictionaries values
<code>pop(key)</code>	Remove key and return previous value
<code>popitem()</code>	Remove and return an arbitrary item
<code>update()</code>	Update key/value pairs from another dictionary

# Tuples as dictionary keys

- A tuple can be used as a dictionary key, and parenthesis can be omitted

```
Python shell -  
> d = {('a', 1): 7, ('b', 2): 42}  
> d[('b', 2)]  
| 42  
> d['b', 2] # same as above, parenthesis omitted  
| 42  
> T = [[None, None], [42, None]] # 2D table as lists-of-lists  
> T[1][0]  
| 42  
> T[1, 0] # wrong, T is a list (of lists)  
| TypeError: list indices must be integers or slices, not tuple  
> T = {(1, 0): 42} # 2D table as dictionary  
> T[1, 0] # dictionary lookup with tuple (1, 0) as key  
| 42  
> T[1][0] # wrong, T has only one key = the tuple (1, 0)  
| KeyError: 1
```

# Order returned by `list(d.keys())` ?

## The Python Standard Library Mapping Types — dict

“Dictionaries preserve insertion order. Note that updating a key does not affect the order. Keys added after deletion are inserted at the end.” (since Python 3.7)

[docs.python.org/3/library/stdtypes.html](https://docs.python.org/3/library/stdtypes.html)

## Python shell

```
> d = {'d': 1, 'c': 2, 'b': 3, 'a': 4}
> d['x'] = 5    # new key at end
> d['c'] = 6    # overwrite value
> del d['b']    # remove key 'b'
> d['b'] = 7    # reinsert key 'b' at end
> d
| {'d': 1, 'c': 6, 'a': 4, 'x': 5, 'b': 7}
```

# Dictionary comprehension

- Similarly to creating a list using list comprehension, one can create a set of key-value pairs:

```
{key : value for variable in list}
```

## Python shell

```
> names = ['Mickey', 'Donald', 'Scrooge']
> list(enumerate(names, start=1))
| [(1, 'Mickey'), (2, 'Donald'), (3, 'Scrooge')]
> dict(enumerate(names, start=1))
| {1: 'Mickey', 2: 'Donald', 3: 'Scrooge'}
> {name: idx for idx, name in enumerate(names, start=1)}
| {'Mickey': 1, 'Donald': 2, 'Scrooge': 3}
```

# Sets (set and frozenset)

{ *value*<sub>1</sub>, ..., *value*<sub>k</sub> }

- Values of type set represent mutable sets, where “==” elements only appear once
- Do not support: indexing, slicing
- frozenset is an immutable version of set

## Python shell

```
> S = {2, 5, 'a', 'c'}
> T = {3, 4, 5, 'c'}
> S | T
| {2, 3, 4, 5, 'a', 'c'}
> S & T
| {5, 'c'}
> S ^ T
| {2, 3, 4, 'a'}
> S - T
| {2, 'a'}
> {4, 5, 5.0, 5.1}
| {4, 5, 5.1}
```

Operation	Description
S   T	Set union
S & T	Set intersection
S - T	Set difference
S ^ T	Symmetric difference
set()	Empty set ( {} = empty dictionary ! )
set(L)	Create set from sequence
x in S	Membership
x not in S	Non-membership
S.isdisjoint(T)	Disjoint sets
S <= T	Subset
S < T	Proper subset
S >= T	Superset
S > T	Proper superset
len(S)	Size of S
S.add(x)	Add x to S (not frozenset)

<https://docs.python.org/3/tutorial/datastructures.html#sets>

<https://docs.python.org/3/library/stdtypes.html#set-types-set-frozenset>

# Question – What value has the expression ?

```
sorted( { 5, 5.5, 5.0, '5' } )
```

- a) { '5', 5, 5.0, 5.5 }
- b) {5, 5.5 }
- c) ['5', 5.0, 5.5 ]
- d) ['5', 5, 5.5 ]
-  e) TypeError
- f) Don't know

# Sets of (frozen) sets

- Sets are mutable, i.e. cannot be used as dictionary keys or elements in sets
- Frozen sets can

## Python shell

```
> S = {{'a'}, {'a', 'b'}, {'a', 'c'}}  
| TypeError: unhashable type: 'set'  
> S = {frozenset({'a'}), frozenset({'a', 'b'}), frozenset({'a', 'c'})}  
> frozenset({'a', 'b'}) in S  
| True  
> {'a', 'b'} in S # automatically converts unhashable set to frozenset  
| True  
> {'a', 'b'} == frozenset(['a', 'b']) # frozenset from list  
| True  
> D = {frozenset({'a', 'b'}): 42} # dictionary  
> frozenset({'a', 'b'}) in D  
| True  
> {'a', 'b'} in D # dictionaries are not that friendly as sets  
| TypeError: unhashable type: 'set'
```

# Set comprehension

- Similarly to creating a list using list comprehension, one can create a set of values (also using nested for- and if-statements):

{*value* for *variable* in *list*}

- A value occurring multiple times as *value* will only be included once

primes\_set.py

```
n = 101
not_primes = {m for f in range(2, n) for m in range(2 * f, n, f)}
primes = set(range(2, n)) - not_primes
```

Python shell

```
> L = ['a', 'b', 'c']
> {(x,(y,z)) for x in L for y in L for z in L if x != y and y != z and z != x}
| {('a',('b','c')),('a',('c','b')),('b',('a','c')),...,('c',('b','a'))}
> L = {'a', 'b', 'c'}
> {(x,(y,z)) for x in L for y in L - {x} for z in L - {x, y}}
| {('c',('b','a')),('c',('a','b')),('a',('c','b')),...,('b',('a','c'))}
```

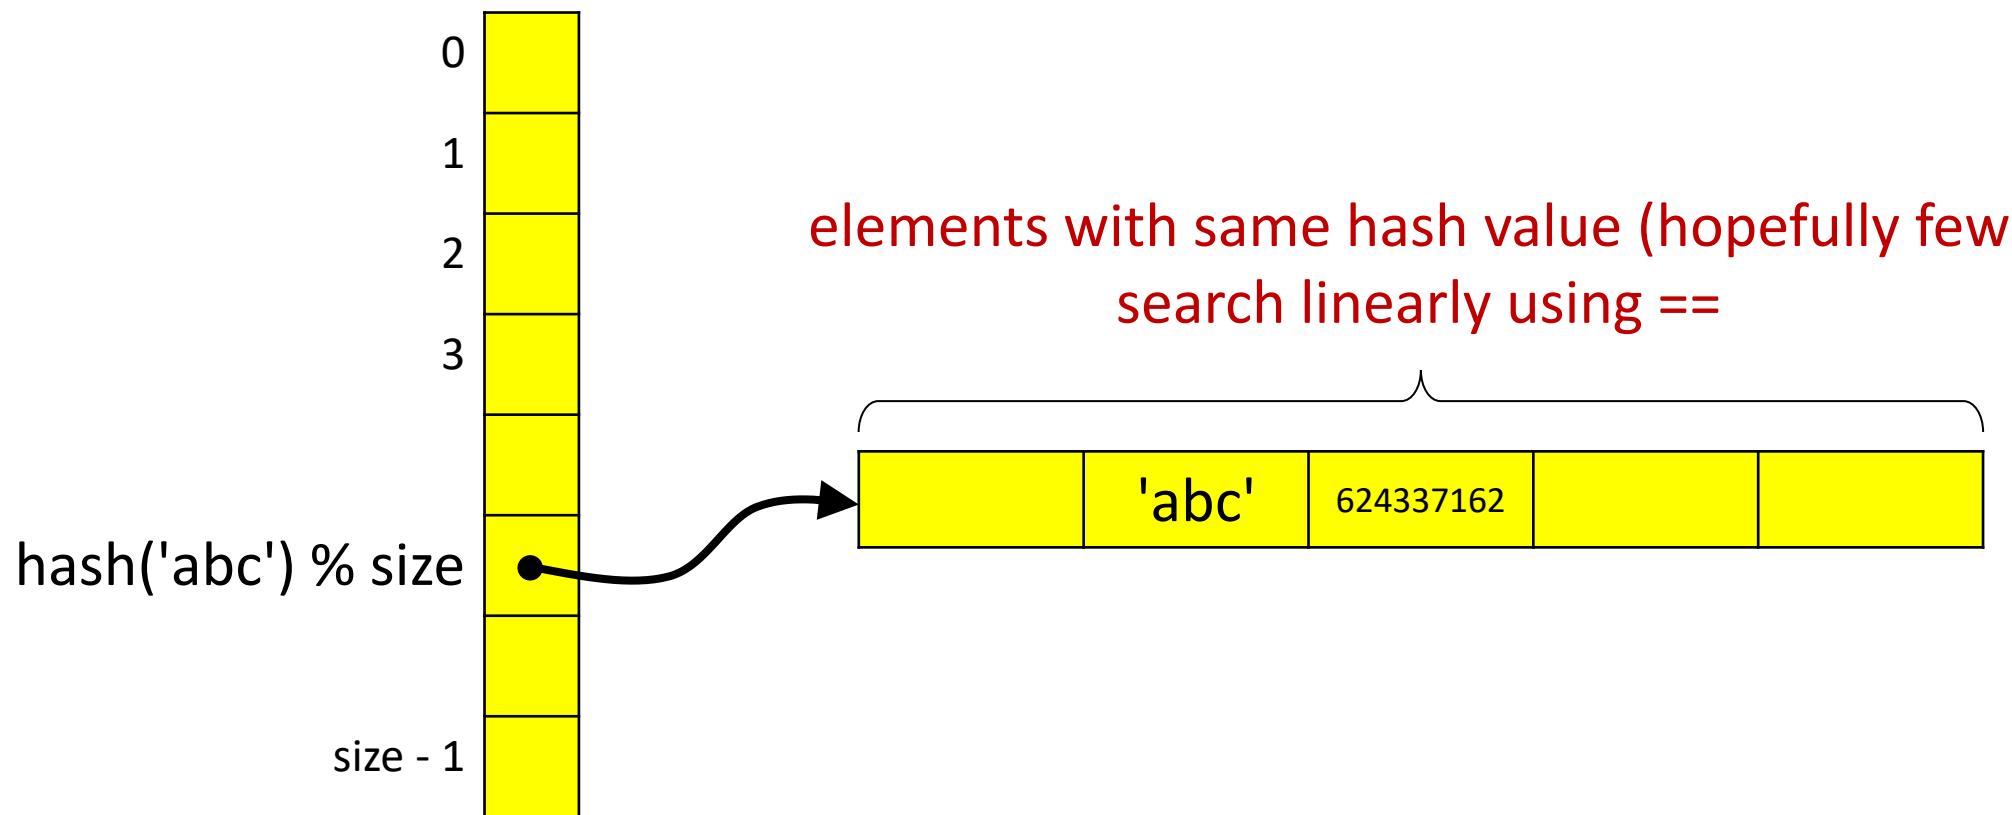

# Hash, equality, and immutability

- Keys for dictionaries and sets must be *hashable*, i.e. have a `__hash__()` method returning an integer that does not change over their lifetime and an `__eq__()` method to check for equality with “==”

```
'abc'.__hash__() could e.g. return 624337162  
(624337162).__hash__() would also return 624337162
```

- All built-in immutable types are hashable. In particular tuples of immutable values are hashable. I.e. trees represented by nested tuples like `((('a'), 'b'), ('c', ('d', 'e')))` can be used as dictionary keys or stored in a set

# Sketch of internal set implementation

Raymond Hettinger,  
*Modern Python Dictionaries*  
- A confluence of a dozen great ideas

# Module **`collections`** (container datatypes)

- Python builtin containers for data: list, tuple, dict, and set.
- The module **`collections`** provides further alternatives  
(but these are not part of the language like the builtin containers)

`deque`

double ended queue

`namedtuple`

tuples allowing access to fields by name

`Counter`

special dictionary to count occurrences of elements

...

# deque – double ended queues

- Extends lists with efficient updates at the front
-  Inserting at the front of a standard Python list takes linear time in the size of the list – very slow for long lists

## Python shell

```
> L = list()
> L.append(1)
> L.append(2)
> L.insert(0, 0)  # insert at the front
> L.insert(0, -1) # slow for long lists
> L.insert(0, -2)
> L
| [-2, -1, 0, 1, 2]
```

```
> from collections import deque
> d = deque()    # create empty deque
> d.append(1)
> d.append(2)
> d.appendleft(0) # efficient
> d.appendleft(-1)
> d.appendleft(-2)
> d
| deque([2, 1, 0, -1, -2])
> for e in d: print(e, end=' ', )
| -2, -1, 0, 1, 2,
```

# namedtuple – tuples with field names

- Compromise between tuple and dict, can increase code readability

## Python shell

```
> person = ('Donald Duck', 1934, '3 feet') # as tuple
> person[1] # not clear what is accessed
| 1934
> person = {'name': 'Donald Duck', 'appeared': 1934, 'height': '3 feet'} # as dict
> person['appeared'] # more clear what is accessed, but [...] overhead
| 1934

> from collections import namedtuple
> Person = namedtuple('Person', ['name', 'appeared', 'height']) # create new type
> person = Person('Donald Duck', 1934, '3 feet') # as namedtuple
> person
| Person(name='Donald Duck', appeared=1934, height='3 feet')
> person.appeared # short and clear
| 1934
> person[1] # still possible
| 1934
```

# Counter – dictionaries for counting

## Python shell

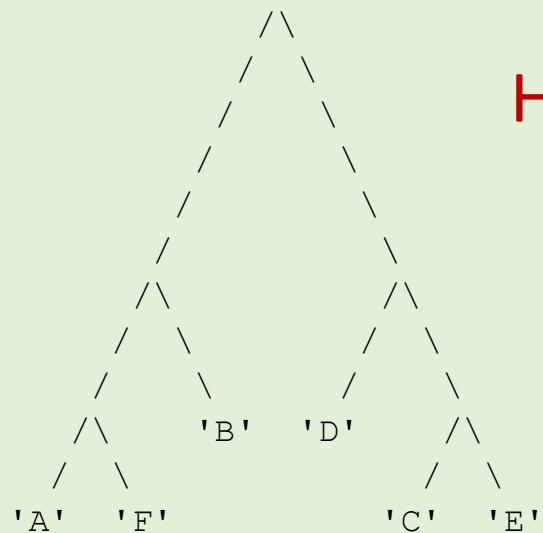

```
> from collections import Counter
> fq = Counter('abracadabra') # create new counter from a sequence
> fq
| Counter({'a': 5, 'b': 2, 'r': 2, 'c': 1, 'd': 1}) # frequencies of the letters
> fq['a']
| 5
> fq.most_common(3)
| [ ('a', 5), ('b', 2), ('r', 2) ]
> fq['x'] += 5 # increase count of 'x', also valid if 'x' not in Counter yet
> Counter('aaabbbcc') - Counter('aabdd') # counters can be subtracted
| Counter({'b': 2, 'c': 2, 'a': 1})
> Counter([1, 2, 1, 3, 4, 5]) + Counter([3, 3, 3]) # counters can be added
| Counter({3: 4, 1: 2, 2: 1, 4: 1, 5: 1})
> T = 'AfD adsf dsa f dsaf daf dsaf DSA fda f SA dsa f dsa fdsa f dsAf sAf f dsaf'
> Counter(T.lower().split()).most_common(3)
| [ ('f', 5), ('dsa', 4), ('dsaf', 4)]
```

# Handin 3 & 4 – Triplet distance (Dobson, 1975)

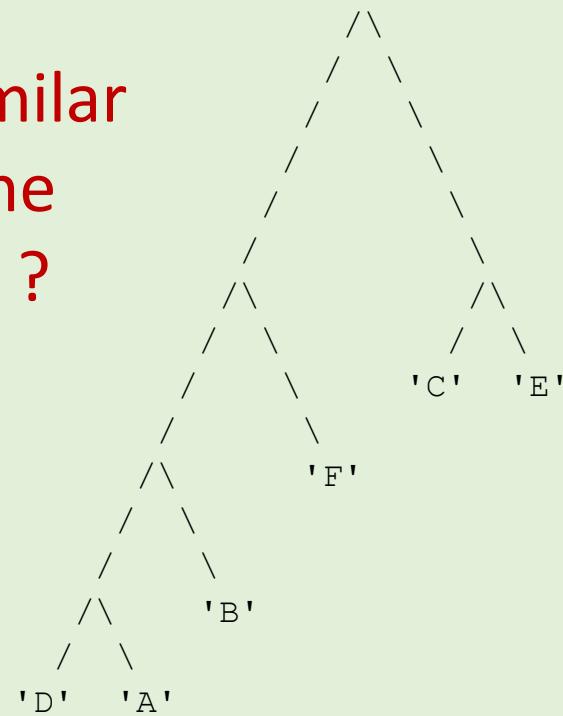

```
(( ('A', 'F'), 'B'), ('D', ('C', 'E'))))
```

```
(( ('D', 'A'), 'B'), 'F'), ('C', 'E'))
```

(a)

(b)

# How similar are the trees ?

# Handin 3 & 4 – Triplet distance (Dobson, 1975)

Consider all  $\binom{n}{3}$  subsets of size three, and count how many do not have identical substructure (topology) in the two trees.
